#### UNDERGROUND CURE FOR ASTHMA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In illustration of the curative effects of the air on the Underground Railway, I remember the case of a man under my care in Victoria Park Hospital. This man had for some time been liable to severe attacks of spasmodic asthma, and one day he told me he must leave the hospital, as the air of the well-ventilated wards caused his breathing to be constantly difficult. I asked him what sort of air agreed best with him, and he replied that he never felt so easy and free from chest oppression as when in one of the tunnels of the Metropolitan Railway.

It is a well-known fact that the smoky air of a town is most beneficial to those who suffer from true spasmodic asthma, with no bronchitic complication.

The inhaled carbon doubtless has an anti-spasmodic action on the spasmodically fixed bronchial muscle. The spasm is overcome, and then easy breathing follows. The medicine I have thought most useful in these cases is belladonna. This same drug we know to be of great service in certain forms of constipation where ordinary purgatives are very unsatisfactory. I have thought that these cases of constipation may be due to spasm of the circular muscular fibres of the intestines, so that in this respect they resemble spasmodic bronchial asthma. Smoking a cigar or pipe is often a means of relief in this form of constipation, as many persons know well by experience.

I am, Sir, yours truly,

JOHN C. THOROWGOOD, M.D., F.R.C.P.,  
Consulting Physician to Victoria Park Chest  
Hospital.

Bognor, November, 1909.

## SPECIAL ARTICLES.

### HEMEL HEMPSTEAD WORKHOUSE.

Princess Christian, patron, and the officers of the Workhouse Nursing Association have addressed the following letter to the Rt. Hon. Mr. Burns on the case of Nurse Bellamy at Hemel Hempstead Workhouse Infirmary:—

Workhouse Nursing Association, Dacre House,  
Dean Farrar Street, Westminster, S.W.

SIR,—We beg your consideration of the following remarks:—

Nurse Bellamy having now been acquitted from the charge of manslaughter for accelerating the death of a male inmate by ordering him a bath, we feel it to be in the public interest to draw attention to the state of things this case disclosed, in the hope that out of evil good may come.

In the first place it exemplifies the deplorable uncertainty of the Local Government Board's orders and rules governing the administration of workhouses and infirmaries, and as a natural, if not necessary, consequence, the laxity of the manner in which effect is given to them, and the grave distress and danger to the inmates which result. In the next place, it is a glaring example of the cruel position in which young women may find themselves who are induced to apply for and obtain the position of nurses in these institutions. We are referring more particularly of course to the smaller and country institutions.

There is a third point to which we desire also to draw particular attention, and that is the practice that obtains in some places, as it does at Hemel Hempstead, for the offices of clerk to the Guardians, Coroner, and clerk to the Justices being all held by the same person. We cannot believe that but for this practice the unfortunate Nurse Bellamy would ever have been on her trial on such a terrible charge as that from which she has just been dismissed. The facts appear shortly to be these:—She had borne the brunt for some time of complaints made to the matron by all the nurses of the excessive work imposed upon them and had herself been before the Guardians on the subject. She had in consequence incurred the displeasure of the matron and the clerk to the Guardians. The inevitable result was that when the trouble arose this gentleman as Coroner ordered an inquest, he proceeded to the inquiry with a bias, if nothing more, against her. This bias is obvious from the newspaper reports (which were very full) of the proceedings and of his summing-up to the jury. As the Coroner did not think it necessary to order a post-mortem, the findings of the jury as to the cause of the deaths followed the doctor's opinion, and the principal object of the inquest became the fixing of responsibility, if any. From the manner in which it was conducted, judging by the reports to which we have referred, one might not unfairly suppose it was undertaken for the express purpose of fixing the responsibility upon Nurse Bellamy, and so to provide a scapegoat for those in authority and for the wholly indefensible system permitted at this institution. But however this may be, the jury did in fact find her guilty, although they are

reported as having taken two hours in coming to their conclusion, during most of which time the Coroner was, we are informed, with them in consultation. Whether this be a regular proceeding or not we do not know, but it seems to us to be in any case highly improper, and in this case was highly significant, that even with the Coroner's assistance the jury should have taken so long a time to come to the conclusion they eventually did. Immediately after her committal the nurse was arrested by the police on their own account on a similar charge, locked up for the night and brought before the magistrates the next morning—the police stating that they had previously had instructions to arrest her whatever the conclusions the jury might arrive at regarding her! The case then came before the Justices as a police prosecution, and their clerk and adviser was the same gentleman who had already dealt with it before the Guardians and as Coroner. She was, of course, committed also by the Justices. But when it came in due time before the grand jury at the assizes, they refused to return a true bill and the case was dismissed. This meant that the grand jury found that the evidence was such that no jury of 12 men could reasonably find Nurse Bellamy guilty of culpable negligence. Under these circumstances the Crown, of course, offered no evidence against her on the Coroner's committal, and the jury accordingly found her not guilty. What a commentary on the Coroner's action! But what of the nurse? Is it nothing that she should have to stand in the dock on such a charge? Is it nothing that she and her family—highly respectable though humble people—should have to undergo the anxiety and suspense imposed upon them for several weeks, not to mention the heavy expense her defence entailed? Fortunately for her, the case aroused such widespread sympathy that many nurses and others—most of them entire strangers to her—have subscribed to a defence fund for her.

It is, indeed, a big blot on the laws of our land that it should be possible for our workhouse sick poor to be subjected to such incompetent and insufficient protection as this case discloses, and that nurses and others should be appointed who are unfit for the discharge of the duties they will be called upon to perform, led by the belief resulting from their appointment that they were fitted, and then subjected to such treatment as Nurse Bellamy has suffered for a misadventure which is not surprising under the conditions which obtained, but which could not have arisen were the laws as they should be, and those appointed under them were properly qualified for their appointment.

We are, on behalf of the Association,

Faithfully yours,

HELENA.

MERIEL S. TALBOT, Vice-President and Chairman of the Executive Committee.

LOUISA TWINING, Vice-President.

J. G. TALBOT, Member of the General Committee.

J. WILSON, Hon. Treasurer.

## MEDICAL NEWS IN BRIEF.

### Royal College of Surgeons of England—Annual Meeting of Fellows and Members.

THE following resolutions are to be moved at the annual meeting of Fellows and members of the Royal College of Surgeons of England, which takes place at the College on Thursday, the 18th inst. The President will take the chair at 3 p.m.

To be moved by Mr. Joseph Smith:—

"That this twenty-fifth annual meeting of Fellows and members again affirms the desirability of admitting members to direct representation on the Council, which as now constituted does not represent the whole Corporation; and that it does so in order that the constitution of the Council of the Royal College of Surgeons of England shall be in keeping with modern ideas of true representation."

To be moved by Dr. A. S. Morton:—

"That, in fulfilment of the promise made by the

President of the College in 1906 this meeting strongly urges the Council to impress upon the Government the necessity of amending the Midwives Act next session, in order that provision may be made to secure just remuneration for professional services rendered by medical men under this Act."

To be moved by Mr. H. Elliot-Blake:—

"That the Council of the Royal College of Surgeons of England, through their Joint Committee of Delegates, and when it is found necessary, and in any agreement with the Royal College of Physicians of London, be asked to approve of and promote a new Charter and Act of Parliament to incorporate the Royal Colleges of Surgeons of England and Physicians of London, so as to form Royal Colleges or parts of the University of London."

### National University of Ireland.

THE Senate met on Thursday, November 11th, and Friday, November 12th.

Sir Christopher Nixon, Bart., M.D., LL.D., was elected the Vice-Chancellor of the University.

The General Board of Studies was constituted, and the Standing Committee and Finance Committee were elected.

Sir Christopher Nixon, Bart., M.D., LL.D., was elected as the Representative of the University on the General Medical Council.

The following resolutions were passed, after consideration of a report from the General Board of Studies:—

1. That for the year 1910 the First University Examination shall not be obligatory on students in Medicine.

2. That for the year 1910 the First University Examination shall not be obligatory on students in Engineering and Music.

3. That all the courses for the Degrees of the Royal University, including those for Matriculation, be adopted for the Examination of the year 1910, in the form in which they would have been for 1910 if the Royal University had continued to exist; but that the practical Examination, Mathematics, Honours, Second University Examination in Arts be discontinued.

(N.B.—The courses for Scholarships and Entrance Exhibitions, Studentships, Junior Fellowships, Medical Studentships, Travelling Medical Scholarship, and Browne Gold Medal and Prize do not come within the scope of this resolution.)

4. That up to December 15th, 1910, the practice which obtained in the Royal University of Ireland of admitting to Matriculation, without further examination, candidates who had passed the Senior Grade Intermediate Examination in the subjects of the Matriculation Examination be continued.

### The London and Counties Medical Protection Society.

A SPECIAL GENERAL MEETING of the members of the London and Counties Medical Protection Society, Limited, will be held, by order of the Council, pursuant to the provisions of Article 9 of the Articles of Association of the Society, on Wednesday, November 24th, 1909, at 4 o'clock in the afternoon, at the registered offices of the Society, No. 31 Craven Street, Strand, London, W.C., for the purposes of considering, and, if thought fit, passing, with or without modification, a resolution to the following effect:—

"To approve the action of the Council in arranging for an insurance of the members of the Society against any damages or costs up to several thousand pounds which may be awarded at any time against any member in any proceedings which the Society may undertake on behalf of its members pursuant to Article 16 of the Articles of Association of the Society, and for that purpose to raise the subscription of the members of the Society to a sum not exceeding £1 per annum."

A large number of the members of the above Society have already effected individual insurance against damages and costs in defensive actions only, and it is now thought desirable to insure the whole of the members of the Society collectively. The insurance can be effected much more satisfactorily when the

Society is insured *en bloc*, and if the above scheme is carried through, a member of the Society will be indemnified against any loss, whether he succeeds or fails in any action, provided only that his case is undertaken by the Council of the Society.

#### Royal College of Surgeons of England.

A QUARTERLY meeting of the trustees of the Hunterian Collection was held on the 10th instant, at the Royal College of Surgeons. Lord Walsingham occupied the chair, and there were also present at the meeting Sir Edward Fry, Sir Douglas Powell (President of the Royal College of Physicians), Mr. Henry T. Butlin (President of the Royal College of Surgeons), Sir John Tweedy, and Professor G. Sims Woodhead (Cambridge). The trustees expressed their sense of the loss the Board had sustained by the death of Sir Thomas Smith. It was decided that the election of a trustee in the vacancy thus occasioned should take place at the meeting of the board in February next. The President of the College presented a report from the conservator of the museum upon the result of a microscopic examination of certain Hunterian specimens.

#### Inquest on Exhumed Body at Accrington.

AN inquest was held at Accrington, on the 2nd inst., on Catherine Morris, 37, single woman, of Accrington, whose body was exhumed from All Saints' burial yard, Clayton-le-Moors, the previous Thursday.

It was stated that the certificate of death given by Dr. Hanna stated the primary cause of death as gastritis.

A post-mortem examination, conducted by Dr. Geddie, of Accrington, and Dr. Briggs, of Blackburn, revealed the cause of death as septic poisoning.

The jury returned a verdict that death was due to blood poisoning arising from after-birth consequent on abortion. There was nothing to show, however, how and when the latter took place.

#### Royal City of Dublin Hospital.

ON the 29th ult. the Countess of Pembroke performed the ceremony of declaring open a new children's ward in the Royal City of Dublin Hospital. The ward is one of several additions made to the hospital, and rendered possible by a grant from the Pembroke Irish Charities Fund.

#### The Royal University of Ireland.

THE following candidates have passed the First Examination in Medicine of the Faculty of Medicine, Autumn, 1909.—Henry Alcock, Charles Bannigan, William W. Blair, Maud S. Budd, Patrick Cagney, Edward P. Carey, David M. Clements, William Deely, John J. Dowdall, Francis W. Doyle, B.A., Joseph Doyle, Sch., Owen J. R. Forde, Edward T. Freeman, Walter F. Hare, Herbert M. Jackson, Thomas Kennedy, Maurice B. King, Marie R. Lynch, William McElroy, Henry McGlaughlin, Mary C. McKenna, B.A., Edward U. MacWilliam, Edward A. M. Magennis, John Mooney, William A. Murphy, Gerald P. O'Donnell, Henry T. O'Neill, Samuel E. Picken, John E. Power, Robert L. Rea, Augustine K. Roche, John A. Sellars, Edward Tempny, Catherine J. Timony.

Honours in Botany.—First Class.—Joseph Doyle, Sch. Second Class.—Edward U. MacWilliam, Robert L. Rea.

Honours in Zoology.—First Class.—Joseph Doyle, Sch. Second Class.—Robert L. Rea, Edward U. MacWilliam.

Honours in Chemistry.—First Class.—Joseph Doyle, Sch., Robert L. Rea. Second Class.—None.

Honours in Experimental Physics.—First Class.—Joseph Doyle, Sch. Second Class.—Robert L. Rea, Edward U. MacWilliam.

Exhibitions.—The following candidates were qualified upon their answering to obtain Exhibitions. The names of those disqualified by standing, or otherwise, are printed in italics.—First Class £20.—Joseph Doyle, Sch. Second Class £10.—*Robert L. Rea.*

The Second Examination in Medicine.—Exhibitions.

—First Class £25. George H. Mahony. Second Class £15.—Patrick J. Walsh.

Honours.—First Class.—George H. Mahony. Second Class.—Patrick J. Walsh.

Upper Pass.—John H. Beverland, Thomas Marron, George R. Naylor.

Pass.—Samuel Acheson, James P. Aiken, Thomas Black, Dominick J. Cannon, Francis L. Cleland, Thomas F. Colfer, Christopher Costello, Daniel J. Enright, Edward H. Fennessy, Llewellyn D. I. Graham, John E. Harford, Richard Hennessy, John R. Henry, John V. Holmes, William J. Hunter, B.A., Frederick Jefferson, James T. Kyle, Charles Lafferty, John McFadden, Edward McSorley, William M. Morris, Herbert V. O'Shea, John F. Rahilly, Walter N. Rishworth, John M. Sheridan, Thomas Smyth, B.A., Stanley P. Stoker, Harold V. Walsh, Samuel E. Watson.

Exempted from further examination in the subjects set opposite their names.—Thomas M. Adamson, Chemistry; William Hickey, Anatomy and Physiology; Thomas F. O'Donoghue, Chemistry; John H. Pollock, Anatomy and Physiology; William Turner, Chemistry.

Dr. Henry Hutchinson Stewart Scholarship in Medicine.—George H. Mahony.

The Third Examination in Medicine.—Exhibitions.—First Class £30.—Joseph O. Hodnett. Second Class £20.—Oriel J. O. O'Hanlon.

Honours.—First Class.—Joseph O. Hodnett. Second Class.—Oriel J. O. O'Hanlon, John C. Johnson, B.A.

Upper Pass.—Frederick Crook, Robert J. McConnell, Henry J. V. Mullane.

Pass.—John L. Brown, Maurice J. Cogan, John F. Craig, Robert C. Cummins, Thomas P. Davy, Alexander J. Dempsey, Ernest S. Dixon, Gerald Fitzgerald, David J. Foley, Homer H. C. Lynch, John Lyons, Thomas J. R. Maguire, Cornelius Martin, William M. Millar, Alfred J. Moran, Denis V. Morris, Mary A. Murphy, William O'Brien, Joseph A. O'Flynn, Eileen M. O'Keefe, John C. Osburne, Joseph Patrick, Joseph Prendiville, Walter N. Rishworth, Thomas G. Rothwell, William J. Smyth, Francis J. D. Twigg, Patrick W. White, William Wilson.

The M.B., B.Ch., B.A.O. Degrees Examination.—Upper Pass.—James A. Brown, James B. Butler, M.A., John J. Gilmore, James A. Hanrahan, Edward G. Kennedy, Ernest W. Kirwan, John M. McCloy, Thomas Scanlan.

Pass.—Charles Alexander, Joseph Anderson, John A. Black, Percy M. J. Brett, Bartly Byrne, Samuel R. Campbell, Francis S. Carson, David S. Clarke, B.A., Aibert V. Craig, William Dickey, William A. Frost, Patrick Hayes, Jeremiah Holland, David Horgan, John C. Houston, David J. Jackson, B.A., Thomas Kennedy, Henry H. MacWilliam, B.A., William Magner, Thomas P. Magnier, Thomas J. S. Moffett, Alexander Patton, B.A., Samuel P. Rea, Jeremiah Reidy, David A. Rice, Alfred M. Thomson.

Exempt from further Examination in Medicine and Midwifery.—John H. Harbison, B.A.

Honours.—In Medicine Group.—First Class.—Edward G. Kennedy, John J. Gilmore, James B. Butler, M.A. Second Class.—John M. McCloy.

In Surgery Group.—First Class.—Edward G. Kennedy, William Dickey. Second Class.—Thomas Scanlan.

In Midwifery Group.—First Class.—Bartly Byrne, Samuel R. Campbell. Second Class.—James A. Hanrahan.

Exhibitions, £21 each.—In Medicine Group.—Edward G. Kennedy. In Surgery Group.—Edward G. Kennedy. In Midwifery Group.—Bartly Byrne.

The M.D. Degree Examination.—John Finnegan, M.B., B.Ch., B.A.O., Samuel J. Killen, M.B., B.Ch., B.A.O., Charles B. Pearson, M.B., B.Ch., B.A.O., Stephen B. Walsh, B.A., D.P.H., M.B., B.Ch., B.A.O., Thomas Walsh, B.A., D.P.H., M.B., B.Ch., B.A.O., Samuel H. Whyte, M.B., B.Ch., B.A.O., James E. Wilson, M.B., B.Ch., B.A.O.

The Medical Studentship.—James M. O'Connor, B.A., M.B., B.Ch., B.A.O.

The Diploma in Mental Diseases Examination.—Daniel Gillespie, M.D.

## NOTICES TO CORRESPONDENTS, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

### WARNING.

MESSRS. WILCOX, JOZEAU AND CO., chemists, 49, Haymarket, S.W., desire to warn members of the medical profession against a man, thinly built, apparently about 40 years of age, shabbily dressed, with a pronounced habit of sniffing, who has been representing himself as their agent and making extraordinary proposals. No such person is in their employ or has had any authority whatsoever to use their name.

**HEMOPHTYSIS.**—Notification of tuberculosis in Ireland is only compulsory in those districts where the local authority, Urban or Rural District Council, has, with the consent of the County Council, adopted Part I. of the Tuberculosis Prevention Act.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 17TH.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Prince of Wales's General Hospital, Tottenham, N.).—Clinics: 2.30 p.m.: Medical Out-patient (Dr. T. R. Whipple); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 p.m.: X-Rays (Dr. H. Pirie).

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m.: Mr. T. P. Legg: Clinique (Surgical). 5.15 p.m.: Mr. Arbuthnot Lane: "Operative Treatment of Fractures."

THURSDAY, NOVEMBER 18TH.

**ROYAL SOCIETY OF MEDICINE (DERMATOLOGICAL SECTION)** (20 Hanover Square, W.).—5 p.m.: Dr. Arthur Whitfield: Localised Scleroderma. And other cases.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynaecological Operations (Dr. A. E. Giles). Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 p.m.: Medical In-patient (Dr. G. P. Chappel).

**HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON)** (Great Ormond Street, W.C.).—4 p.m.: Lecture (Medical): Dr. Thompson: Pyelitis in Infancy.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 p.m.: Dr. Francis Warner: "Backward Children and their Training."

**ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN** (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture: Syphilis: Treatment (Constitutional and Local in all its forms).

FRIDAY, NOVEMBER 19TH.

**ROYAL SOCIETY OF MEDICINE (ELECTRO-THERAPEUTICAL SECTION)** (20 Hanover Square, W.).—8.30 p.m.: Dr. Reginald Morton: The Treatment of Nævi and other Cutaneous Lesions by Electrolysis, Caustery and Refrigeration, with a Demonstration on the Use of Solid Carbon Dioxide.

**SOCIETY OF TROPICAL MEDICINE AND HYGIENE** (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Dr. W. Thomas: (1) Oesophagostomiasis in Man (with specimens); (2) The Results of Experiments on Apes, Monkeys, Guinea Pigs, etc., when inoculated with Virulent Blood of Yellow Fever Cases or by the Bites of Infected Stegomyia calopus; (3) Mossy Foot of the Amazon Region (with microscopic specimens); (4) Notes on Stimson's Spirochæte Found in the Kidney of a Yellow Fever Case. (With epidiascope demonstrations.)—Paper (with specimens) will be read for Dr. J. Numa Rat, St. Kitts, W.I., on the So-called Guinea Worm of the Island of Nevis.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinique: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Operations Clinique: Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 p.m.: Medical In-patient (Dr. R. M. Leslie).

**CENTRAL LONDON THROAT AND EAR HOSPITAL** (Gray's Inn Road, W.C.).—3.45 p.m.: Lecture: Dr. D. McKenzie: External Ear.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m.: Mr. H. L. Eason: Clinique (Eye).

MONDAY, NOVEMBER 22ND.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m.: Dr. Wilfred Fox: Clinique (Skin). 5.15 p.m.: Dr. F. J. McCann: "Lecture-Demonstration on the Methods of Suturing a Ruptured Perineum."

TUESDAY, NOVEMBER 23RD.

**CENTRAL LONDON THROAT AND EAR HOSPITAL** (Gray's Inn Road, W.C.).—3.45 p.m.: Trephoscopy, etc.: Mr. Gay French.  
**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m.: Dr. Guthrie Rankin: Clinique (Medical). 5.15 p.m.: Dr. Theo. Hyslop: "Diagnosis of Insanity."

## Appointments.

**BEARN, A. RUSSELL, M.B., Ch.B. Edin.**, House Physician at the Hampstead General Hospital.

**CATES, JOSEPH, M.D. Lond., D.P.H. Camb.**, Assistant Medical Officer of Health to the City of Coventry.

**DALY, ASHLEY S., M.R.C.S., L.R.C.P. Lond.**, Assistant Anaesthetist to the London Hospital.

**FITZGERALD, F. C., L.R.C.S. (Irel.), L.A.H. Dub.**, Certifying Surgeon under the Factory and Workshop Act for the Newtownbutler District of the county of Fermanagh.

**GEORGEON, J. W.**, Certifying Surgeon under the Factory and Workshop Act for the Lauder District of the county of Berwick.

**HEY, WILSON H., F.R.C.S. Eng., M.B., Ch.B. Vict.**, Resident Surgical Officer at the Manchester Royal Infirmary.

**LLOYD, D. G., M.R.C.S., L.R.C.P. Lond.**, Medical Officer to the Llanfyrnach Rural District Council.

**MUMFORD, WILFRED G., M.R. Lond., F.R.C.S. Eng.**, Honorary Assistant Surgeon to the Royal United Hospital, Bath.

**PRICE, J. T., M.D. Dub.**, Certifying Surgeon under the Factory and Workshop Act for the Llansawel District of the county of Carmarthen.

**STEPHEN, W. LEONE, Junior House Physician at the Prince of Wales's General Hospital, N.**

## Vacancies.

**Nottingham General Dispensary.**—Assistant Resident Surgeon. Salary £170 per annum, with apartments, attendance, light, and fuel. Applications to C. Cheesman, Secretary, 12 Low Pavement, Nottingham.

**Nottingham General Dispensary.**—Resident Surgeon. Salary £200 per annum, with apartments, attendance, light, and fuel. Applications to C. Cheesman, Secretary, 12 Low Pavement, Nottingham.

**Manchester Children's Hospital, Out-Patients' Department, Gartside Street, Manchester.**—Medical Officer. Salary £180 per annum. Applications to H. J. Eason, Secretary.

**Whitechapel Union.**—First Assistant Resident Medical Officer. Salary £130 per annum, with rations, furnished apartments, coal, gas, and washing. Applications to F. J. Toole, Clerk to the Guardians, Union Offices, 74 Vallance Road, Whitechapel, N.E.

**Newcastle-upon-Tyne City Lunatic Asylum, Gosforth, Newcastle-upon-Tyne.**—Junior Assistant Medical Officer. Salary £140 per annum, with furnished apartments, board, and laundry. Applications to Dr. Calcott, Medical Superintendent.

**Newcastle-upon-Tyne Dispensary.**—Visiting Medical Assistant. Salary £160 per annum. Applications to the Hon. Secretary, Joseph Carr, Chartered Accountant, 26 Mosley Street, Newcastle-upon-Tyne.

**Pembrokeshire.**—County Medical Officer of Health. Salary £400 a year, and £50 a year for travelling and all other expenses. Applications to Wm. Davies George, Clerk to the County Council, Shire Hall, Haverfordwest.

## Births.

**CRIDLAND.**—On Nov. 10th, at 52 Waterloo Road, Wolverhampton, the wife of Arthur Bernard Cridland, F.R.C.S.E., of a son.

**HANSON.**—On Nov. 13th, at 1 Hurley Street, London, W., the wife of Reginald John Edward Hanson, M.A. Cantab, F.R.C.S.E., and of Hayling Island, Hants, of a daughter.

**FAIRLIE CLARKE.**—On Nov. 12th, at Sussex Lodge, Hortham, the wife of A. J. Fairlie Clarke, M.C., F.R.C.S., of a daughter.

## Marriages.

**JONES—ROBINSON.**—On Nov. 11th, at Emmanuel Church, West Hampstead, Macnaughton Macnaughton-Jones, M.B., second son of Dr. Macnaughton-Jones, of 131 Harley Street, London, and Isabel Jessie Robinson, widow of Ernest Hugo Robinson, and elder daughter of the late Samuel Pownceby, of Hampstead, and Mrs. Pownceby, 11 Bracknell Gardens, London.

**EVERIDGE—ROBERTSON.**—On Nov. 11th, at Saint Mary's Church, East Molesley, John Everidge, M.R.C.S., L.R.C.P., son of the late James Walter Everidge, of Surbiton, to Kathleen Isabel, only daughter of the late Henry James Robertson, J.P., of Grove House, East Molesley.

**PORTER—RAYNER.**—On Nov. 13th, at St. Mary's Church, Hornsey, William James Porter, M.B., Ch.B., of Dundee, New Zealand, to Edith, third daughter of Mr. and Mrs. Richard Rayner, "Cintra," Hornsey.

## Deaths.

**CASTANEDA.**—On Nov. 8th, Dr. M. Castaneda, M.B., M.R.C.P., late chairman of the Italian Hospital, Queen Square.

**MARSHALL.**—On Nov. 11th, at the Homestead, Teddington, Middlesex, Mary A., the wife of John J. de Zouche Marshall, L.R.C.S.I., and eldest daughter of the late Benjamin Warwick, of "The Lodge," Englefield Green, Surrey, in her 60th year.

**THOMSON.**—On Nov. 13th, at 54 St. Stephen's Green, Dublin, of heart disease, in his 65th year, Sir William Thomson, C.B., Hon. Surgeon to His Majesty the King.

## NOTES AND COMMENTS.

### One-portal Qualification.

THE rivalry of the multiple medical corporations is tending towards the inevitable goal of a single qualification for medical men. The competition of the provincial universities and the unreasonable conditions of the London University degree have gradually brought about the present position of affairs. Medical practitioners want a degree, not a mere qualification to practice, and they can get what they want in the provincial universities. The colleges, moreover, have kept their diplomates of the lower rank at arm's length, and have retained the government in the hands of a small and irresponsible favoured class. They also control the General Medical Council by their nominees, to the exclusion of the main body of general practitioners. Hence we have the spectacle of medical students deserting the ancient colleges and schools and flocking to the modern, well-equipped, and comparatively democratic universities. London has had the game in her hands, so far as England is concerned, for the last 400 years, but it now looks as if the curious mediæval system of close corporations has received its death-blow. Yet, notwithstanding the enemy at their gates, the Royal Colleges in all three kingdoms do not appear anxious to capitulate. The garrison seems resolved to face the slow and painful process of starvation rather than to concede such latterday privileges as representative control and co-operation with their rivals in the interests of the public.

### All in the Same Boat.

At the annual meeting of the Royal College of Surgeons of England, last week, the members made the most of their yearly opportunity of protest. They clamoured for direct representation of members on the Council; they protested against the inaction of the College in the control of quack medicines; they insisted on the necessity of amending the Midwives Act; they advocated incorporation with the University of London. Similar views have been advanced on former occasions, but the College has never shown the least sign of being influenced by them. Nor is the Royal College of Physicians of London less aloof and out of touch with modern life. The Royal College of Surgeons of Edinburgh has refused its licentiates the boon of membership, so as to place them on an equal footing of qualification with colleges that grant a membership. Both the Royal Colleges of Physicians and of Surgeons of Edinburgh unite in excluding the lower ranks of their diplomates, whose payments have probably contributed the bulk of their income, from any voice in their own government or representation on the General Medical Council. Practically the same

tale applies all round to the rest of the diploma-granting bodies. Now that the provincial universities have appeared on the scene, the diploma-granting bodies may be brought to reason. Meanwhile, the medical student who is wise in his generation prefers the provincial university with a degree at the end of his course therein to the ancient college or hall that takes his money, grants him a qualification, and then drops his acquaintance unless he has taken the higher diploma.

### The Hemel Hempstead Case.

THE letter of the Workhouse Nursing Association with regard to the Hemel Hempstead Workhouse has been met by a protest from the Justices of the Dacorum Division of Hertfordshire. They met and framed a resolution—published in the *Times* of November 18th—emphatically protesting against the statements contained in the Association's letter reflecting upon the action of the Clerk to the Justices. "They greatly regret that currency has been given to charges which any reasonable inquiry would have shown to be without foundation." At the same meeting the Justices' Clerk intimated that, so far as he was personally concerned, the matter was by no means at an end. The pith of the letter published by the Workhouse Nursing Association appears to lie in their contention that it is undesirable for the posts of Coroner, of Clerk to the Guardians, and of Clerk to the Justices to be vested in one individual. On general grounds, there certainly appears to be a *prima facie* reasonableness in the protest against a plurality of the kind in question. At any rate, the matter seems worthy of some public attention and discussion, in order that a trustworthy conclusion may be formed as to the desirability or otherwise of this sort of multiple officialdom.

### Who is to Blame?

A CASE of chloroform poisoning of a child, aged five years, at Denaby, was last week reported in the *Sheffield Daily Telegraph*. The evidence showed that the wife of a collier procured, for the relief of toothache, a "bottle" of chloroform, which she left on a mantelpiece. Early in the morning two children living in the house stole down into the kitchen. The elder of the two, a boy of eight, got down the bottle and drank some of the contents and gave some to his little sister, who cried for it. No medical man was called until some hours later, when the girl became drowsy. The Coroner censured the person who had left the chloroform on the mantelpiece, but surely the key to this and many other cases of accidental and intentional poisoning lies in the laxity in which dangerous

drugs are sold to the public. What sane and responsible medical man would entrust anyone with a quantity of chloroform sufficient to kill, say, several children? If it comes to that, we doubt if the use of chloroform as a local application for toothache is justifiable on therapeutic grounds. At any rate, we feel safe in asserting strenuously that so potent a drug should be dispensed only on the written authority of a qualified medical practitioner, and that its sale should be guarded as that of any other poison. Perhaps the Pharmaceutical Society will take action on the strength of this occurrence. Meanwhile the attention of the Denaby Coroner may be drawn to this view of the ultimate responsibility in tragedies of this kind.

**Dr. Freyberger**  
as a Public  
Educator.

FROM time to time the public newspapers are illumined by pathological tit-bits culled from the evidence of Dr. Freyberger. When, some years ago, Mr. Coroner Troutbeck, taking his courage in both hands, ignored the medical practitioners of his district in favour of an "expert," it was only natural that the performances of the latter should be watched with a somewhat critical eye. When the members of a learned profession are ousted on the implied ground of their incompetency to ascertain the cause of death on post-mortem and other evidence, it is inevitable that they should want to know the reason why? One of the most recent of Dr. Freyberger's statements that appear to have stimulated the journalistic imagination of Fleet Street is to the effect that a certain deceased person might have lived for some time had his stomach been removed. A fact of that kind is painfully familiar to the medical practitioner who is called upon to treat daily that commonest of cancerous conditions, carcinoma of the stomach. Why Mr. Troutbeck, almost alone of coroners, should demand the special services of a whole-time expert pathologist to impart information of this kind is somewhat of a mystery. If the medical men of his district are qualified to diagnose the maladies of fellow human beings during life, surely they should be able to interpret the facts of the post-mortem room with sufficient accuracy for all practical inquest purposes. If they are not thus competent there must be something radically wrong with the system of medical education and examination.

## LEADING ARTICLES.

### THE GOAL OF ONE-PORTAL QUALIFICATION.

SINCE the time when King Henry VIII. was wise enough to establish a legal medical qualification, there has elapsed a period of nearly 400 years. He clearly recognised that the creation of a properly trained and attested class of practitioners involved as a necessary corollary the rigorous repression of unqualified pretenders. He accordingly conferred upon the Royal College of Physicians of London the right of granting licences to practice, together with well-nigh unbounded summary powers for the punishment and restraint of quacks and of false remedies. These powers and duties were later, in whole or in part, extended to the whole of England. Corresponding powers, duties and privileges were conferred at various times upon similar corporations

in Scotland and Ireland, a fact that is natural enough when we take into consideration the much stronger national individualism that in former times stamped the relationship between the countries now included within the title, the United Kingdom of Great Britain and Ireland. At present we purpose dealing with England. Not long after—according to some authorities, at the same period—the College of Surgeons came into existence, and the apothecaries were differentiated, but gradually there grew up three licensing corporations, the physicians for medicine, the surgeons for surgery, and the apothecaries, who license in both faculties. Quite recently the Royal Colleges of Physicians of London and of the Surgeons of England have combined to give a conjoint diploma. Another comparatively modern creation has been the University of London, an examining, but not a teaching, body, with a high standard of examination knowledge. The history of the jealousies and rivalries and selfishness of the various licensing bodies would require a book of ponderous dimensions. Suffice it to say that the one effort of each and every corporation appears to have been to make confusion worse confounded, and to sacrifice the interests of the public and of the medical profession to those of colleges and halls, and of the individuals into whose hands the autocratic control of those bodies had drifted. Some idea of the present position may be gathered from the proceedings at the annual meeting of the Royal College of Surgeons last week. The members, who are excluded from any voice in the government of the College, number 17,000, and, as usual, took advantage of the occasion to protest against their exclusion, which, as one speaker remarked, is "not in keeping with modern ideas of representation." Another speaker pointed out that "the present position produced friction, animosities and bad feeling, which was detrimental to the whole profession." A motion in favour of admitting members to representation on the Council was carried *nem. con.*, but it seems doubtful, in view of previous experiences, whether the resolution will have the least practical outcome. Another ominous resolution was carried to the effect that the Council be asked to promote, if necessary in conjunction with the Physicians, a Bill to amalgamate the Colleges of Physicians and Surgeons, either alone or as parts of the University of London. From this meeting it seems clear that the democracy of medicine is overwhelmingly in favour of the reduction of licensing bodies; in other words, they have practically adopted the principle of the one-portal system. On the other hand, the President of the College, Mr. H. T. Butlin, appears to have adopted the usual *non possumus* official attitude as regards the members. While he admitted that London students suffered great disadvantage through the want of a degree, he was doubtful as to whether any arrangement could be entered into with the University of London. Almost at the same time we find a Fellow of the Royal College of Surgeons, Mr. A. T. Norton, C.B., and an examiner in surgery at the Apothecaries' Hall, advocating much the same thing. Speaking at the annual dinner of the Apothecaries' Society, he said that the want of a

London medical degree on reasonable terms was driving away the students to an extent that became a catastrophe to the various licensing bodies. He urged the creation of a new university, to be called the State University of Medicine, to grant one degree in medicine and in surgery. Under this university should be incorporated all the diploma-granting bodies in the United Kingdom. That is our old friend, the one-portal system, under a somewhat thin disguise, brought before the public under somewhat altered circumstances. The "diploma-granting bodies" of the kingdom—to put the matter bluntly—are threatened with extinction owing to the competition of provincial universities which grant a degree in medicine and surgery on reasonable terms. It is somewhat interesting to note the attitude of the ancient corporations still refusing to fall in with modern views as to representative control, and still clinging to their ancient traditions of oligarchy and aloofness. The Councils of the Scotch and Irish Colleges also exclude their diplomates of lower rank from their councils; nay, what is more, they nominate members of their own oligarchies on the General Medical Council, which is thereby rendered representative of a small governing class and not of the whole profession. It looks, however, as if the days of close corporations and of class government were coming to a close in the medical world, and the one-portal system of qualification emerging into the arena of practical politics.

#### MARTYRS TO SCIENCE.

FOR the achievement of great results science must not be pursued in a spirit of narrow utilitarianism. The worker must not be perpetually asking himself what is the practical value of this or that fact; to establish truth must be his sole desire and aim; and he must be satisfied with the reflection that there was never yet discovered a single new fact, isolated or useless as it might at first appear, that did not in the end fall into place as an indispensable atom in the sum of knowledge upon which advancement depends. The cultivation of science in this spirit calls for rare devotion and self-sacrifice. In any worldly sense, it is very seldom in the least remunerative, and it seldom brings either popularity or fame. It must be borne in mind that it is only within the last thirty or forty years that science has been afforded any place in our educational system, and secured the position to which it is entitled in our ancient Universities. Even now a great proportion of our youth from among whom governing classes and statesmen are selected pass through school and college without any instruction in science whatever. Scientific research of the highest quality can rarely be done to order, and, indeed, no superlatively great work in science, art, or literature was ever produced under such conditions. True genius will not be tempted by wealth, nor will it be turned from its bent by anything short of starvation and death. It is impossible to know how many martyrs to science—men whose lives are silently sacrificed in this form of service to humanity—the years produce, but that some do sink beneath the weight of

their self-imposed burden there can be no doubt. Nothing came out more clearly in the biography of Darwin than the fact that had he not possessed resources which enabled him to guard his health and husband his feeble strength, and concentrate his powers on the tasks he set himself, he could not have formulated more than a fragment of the epoch-making theories he at last constructed. It is, however, more than difficult to suggest a scheme whereby developing talent or genius might be recognised and guarded at the public charge. It is at present impossible to make the great body of the people understand the purpose or utility of abstract science, or to recognise merit in those who labour at it. It is always impossible to find more than a few people in any class of society who are acquainted with the names, much less with the work of contemporary men of science, upon whose success the world's forward movement may depend. Whilst, however, genius is rare, talent and industry are comparatively common, and the question how best to help investigators to pursue lines of research for which they may have displayed fitness is assuming more and more prominence. The Government annual grants, administered through the Royal Society, which are now being advertised, form one of the signs of the times. It would be an enormous encouragement to science-workers if they could be made to feel that should want overtake them, or should they die and leave their families in need owing to their devotion to their calling, the State would intervene with adequate help. It ought never to be necessary to appeal to the charitable public in cases like those of Dr. Herbert Wells and of the non-medical expert, Mr. H. W. Cox, the one who has just died, and the other who has suffered mutilation—pure martyrdom in the cause of science.

#### CURRENT TOPICS.

##### Medical Referees and the Compensation Act.

AN important judgment was delivered in a stated case heard by four Scotch judges in the Second Division. A miner who was injured on February 25th, 1907, was paid compensation by agreement until October 20th, 1908. Payment was then stopped, and on November 3rd, 1908, the parties applied to the Sheriff for a remit to a medical referee, who reported that incapacity had ceased on October 20th, 1908. The plaintiff apparently acquiesced until May, 1909, when he said incapacity had recurred, and applied for renewal of compensation. In defence it was pleaded that the report of the medical referee was conclusive, and barred the claim. That view was accepted by the Sheriff, who, however, stated a case for the opinion of the higher court. The Division answered that the decision of the medical referee did not bar the pursuer's application for arbitration. The gist of the decision was apparently that, in the words of Lord Justice Clerk, the effect of a referee's report was conclusive evidence of something, and nothing more; that it was in no sense a decision. The report might be made the basis of arbitration or of other legal proceedings. This

judgment—United Collieries, Ltd., and George King—is of importance as defining the powers of the medical referee. As Lord Ardwell remarked, nothing could be predicated as necessarily certain under that Act or any proceedings under it. We presume the miner will now apply to the Sheriff for compensation once more, in spite of the previous adverse opinion of the medical referee.

#### **Veterinary Surgeons and Public Health.**

WITH the growth of sanitary science and the increased knowledge of the diseases of animals communicated to man, a closer association has arisen between the medical and veterinary professions. The assistance of veterinary surgeons has naturally proved of great effect in public health administration, and for such duties as the inspection of milch cows and of meat they are by their education peculiarly fitted. Nevertheless, the position to be occupied by the veterinary surgeon in public health work should be clearly defined, and we believe it should never be other than that of assistant or consultant to the medical officer of health. As soon as he is given an independent position confusion arises, and we have the anomaly of dual control of the public health of a district. This is unfortunately the position created recently in Ireland by the action of the Local Government Board, who have authorised the appointment of veterinary surgeons as inspectors of cowsheds and dairies, to hold office and perform their duties independently of the medical officer of health of the district. If the public health is to be preserved, its care must be in the hands of one officer who should be supplied with whatever assistance is necessary, but it is foolish in the extreme to appoint two independent officers whose duties are bound to overlap.

#### **The Passing of the Royal University.**

THE Royal University of Ireland, after an existence of thirty years, has ceased to be. For many years it was obvious that it failed adequately to supply what was needed in Irish education and that in any re-organisation of Irish University education, its individuality was bound to disappear. Its failure was inherent in its constitution, for, like some other enterprises in Irish education, it was built on a model already becoming obsolete in England. Like the old London University, the Royal University was in essence an examining board, and it was a curious blunder in statesmanship to start such an institution in Ireland at the very time when its weakness was becoming evident in London. Nevertheless, while observing the necessary failure of the Royal University, it would be unjust not to give praise to the high ideals of those to whose hands the work of the University was committed, and to the energy and ability shown in its administration. From the first a high standard of knowledge—in medicine as in other subjects—was demanded, and this standard had its effect on the other educational bodies in Ireland. In the thirty years of its life, it gave the seal of its degrees to many men who have become distinguished in science, in literature, and in public

life. Moreover, though the faults in its constitution were grave, the Royal University offered the possibility of education to many to whom knowledge would otherwise have been a sealed book. It has now given place to two universities, full of life, vigour and promise. Their success seems assured, but some at least of that success will be due to their predecessor, whose high standard we are sure they will maintain.

#### **Health of the Paris Garrison.**

SOME weeks ago the vital statistics of Paris, London and Berlin were contrasted in these columns much to the disadvantage of Paris. In La Ville Lumière, the city of light, as her inhabitants are proud to style her, everything has been sacrificed to art and beauty. From the high architectural point of view Paris is a superb city, but from the point of view of sanitary science there is much behind the scenes that is retrograde, obsolete and barbarous. The health of the troops as lately described in a report to the Academy of Medicine, extending over four years and prepared by the medical staff, is worse than that of the civil population. The report contrasts the statistics of the Paris garrison with those of the troops in Berlin. In Paris there are 45,000 men in barracks, in Berlin 65,000. The French mortality is so much greater, that with an effective force equal to that of Berlin the deaths would be as heavy as those in the entire German army. The figures with regard to measles, influenza, and consumption show an enormous disproportion of deaths between the Paris and Berlin garrisons, whilst the Paris typhoid fever statistics are truly shocking, the mortality being ten times greater than in Berlin. The number of dysentery cases in Paris, during the four years was twice as large as that in the whole German army. The general unhealthiness of Paris is set down as a prime cause of the trouble, but it is also stated that the barracks are in most cases old and dilapidated. Several date from the 16th and 17th centuries, and are as much below the requirements of modern hygiene as the fortifications of Vauban are below the necessities of present day warfare.

#### **Abortion-Mongering in Lancashire.**

A WELL-KNOWN Lancashire medical officer of health sends us a batch of local papers containing recent reports of cases in coroners' and police courts which seem to indicate that the trade in procuring abortion must be in a flourishing condition in the County Palatine. In the coroners' courts numerous cases have been investigated of deaths following miscarriage in which the medical men have formed grave suspicions of foul play, but in which, although the autopsies have confirmed the grounds for suspicion, enough evidence has not been forthcoming to support a criminal charge. In two cases rumours having reached the practitioners who had certified the deaths that criminal methods had been adopted, the bodies were exhumed, and inquests held, without however, fixing the guilt upon any person. In several cases women are awaiting trial at the assizes charged with using instruments or administering noxious drugs. Female quack practitioners, sometimes in the garb of hospital

nurses, we are informed, are to be found in many market places. Here in handbills and with loud voice, they proclaim the virtues of their "famous female pills, warranted to remove all obstructions," and explain the efficacy of their "special pessaries a harmless, sure, and safe preventive." Giving evidence in one case Dr. Willcocks, the Home Office Analyst, proved that the "female pills" each contained 1.9 grains of aloes. They were prescribed to be taken three at bedtime and three in the morning, a sufficiently drastic dose, if continued, and decidedly calculated to produce the desired effect!

#### English Winter Climates.

At this season a newspaper correspondence on the advantages to invalids of English winter resorts seems now to have become a regular phenomenon, and whilst there is sometimes displayed an over-anxiety to advertise the merits of this or that locality, there can be no doubt about the truth of the general statement, that a large proportion of the invalids who now winter abroad could find in the South of England every climatic advantage their particular malady calls for. The cases need, of course, selecting. These islands do not offer the climatic peculiarities of the Nile Valley, or of Sicily, or of Algiers, or of the West Indies, any of which may be most suitable in certain forms of disease; but for those which demand simply an outdoor life, with a moderate temperature, and a fair amount of sunshine, every requirement can be found at home. And it is not only in the large towns that the delicate visitor is now catered for. There is hardly a small town or village favourably situated round the South-West coasts which does not offer accommodation in the way of hotels and lodgings calculated to satisfy any but an ultra-fastidious taste. It ought to be borne in mind, also, but it is often forgotten, that a great many invalids who may obey without protest the medical command for winter banishment, go away with pain at the heart, and continuously suffer whilst abroad all the pangs of home-sickness. They fret at separation from those near and dear to them, and this very often is enough to counteract all the good the change should do them. This feeling does not, of course, arise when patients of this type remain in England, where very often families may continue united, or the invalid may be, at least, within easy reach of a week-end visitor.

#### Bacteriology under the Hammer.

DISCUSSING various bacteriological appointments likely to be made under the Tuberculosis Prevention (Ireland) Act, we expressed the hope some weeks ago that such appointments should be made on terms suitable to the medical profession. In particular, we hoped that they would not be put up to be tendered for at competitive rates, like contracts to supply potatoes or to mend roads. So far, we have only observed two public bodies advertising for bacteriologists—the Corporation of Dublin and the County Dublin County Council. The latter has invited applications for the post, remuneration to be made at a certain fixed fee for each specimen submitted. The fee, though by no means generous, is not unreasonable when one compares it with the fees charged for similar work by the owners of clinical research laboratories. The Corporation of Dublin has, however, adopted what appears to us a much more objectionable plan. Candidates are requested to state the fees for which they are prepared to undertake certain specified investigations, such tenders apparently to have a bearing on their candidature. We presume that, as is usual in the consideration of tenders,

the lowest tender is not necessarily accepted, but we think the method of selection is nearly as bad as could be adopted.

### PERSONAL.

HIS MAJESTY THE KING has conferred upon Dr. de Mello Breyner, Physician in Ordinary to King Manuel, the Companionship of the Royal Victorian Order.

THE KING sent a number of pictures to the art loan exhibition opened in Lynn on the 19th inst. on behalf of the West Norfolk and Lynn Hospital. The Queen has sent exhibits from the art schools at Sandringham, and the Princess of Wales has lent several articles.

THE PRINCE OF WALES has sent a cheque for £50 towards the funds of the hospital. His Royal Highness is lending thirteen silver models of ships.

THE KAISER has sent a donation of £50 to the Seamen's Hospital Society ("Dreadnought"), Greenwich.

THE appointment of Medical Inspector of Recruits for the Aldershot Command has been abolished.

SIR W. T. THOMPSON, M.D., has been appointed Registrar-General for Ireland.

MR. V. WARREN LOW, M.D., B.S., F.R.C.S., has been appointed a surgeon at St. Mary's Hospital.

MR. R. MILLER, M.D., B.S., M.R.C.P., has been appointed assistant physician, also at St. Mary's Hospital.

THE directors of the Eye Infirmary, Glasgow, have appointed Dr. Arthur J. Ballantyne, surgeon to the infirmary, to fill the vacancy caused by the death of Dr. T. S. Meighan.

DR. PHILIP BAHR and some students of the London School for the Study of Tropical Medicine left for Fiji to study dysentery, on November 19th. The money for the expedition is being provided by the family of Lord Sheffield.

THE new balconies presented to the West Suffolk General Hospital, Bury St. Edmunds, by Mr. and Mrs. Washington Charters, and the out-patients' department were opened for use on October 23rd by Earl Cadogan, the hospital's president.

THE vacancy in the Skin Department at University College Hospital has been filled by the appointment of Dr. A. M. H. Gray, M.D., M.R.C.P., F.R.C.S., to be Physician for Skin Diseases.

SIR THOMAS BARLOW presided at the annual dinner of Past and Present Students of the National Dental Hospital on November 19th at the Trocadero Restaurant.

SIR HENRY W. NEWTON, who received his knighthood on the King's Birthday, was born in the year 1842, his father being a well-known medical practitioner in Newcastle. He is a "father" of the city council, having entered that body in 1866. He has been a sheriff of Newcastle, and has twice held the office of mayor.

THE Aston Guardians have decided on the suspension of Dr. May from the post of District Medical Officer. The gentleman in question disappeared from home mysteriously on October 15th, and we understand has not since been heard of.

MR. ERNEST WATT, M.D., D.P.H., senior assistant medical officer of the county and sanitary districts of Lanarkshire, has been appointed Medical Officer of Health for Partick, Superintendent of Knightswood Hospital, and Police Surgeon.

# A CLINICAL LECTURE

## ON

### THE EXAMINATION OF THE PERSON. (a)

By FRED J. SMITH, M.D.,

Physician, London Hospital.

GENTLEMEN,—I must apologise for taking you out of the ordinary routine of clinical medicine here, but the subject on which I wish to talk to you is one which you are not likely to pick up unless you do listen to a lecture on it. In your daily practice, what happens in 999 cases out of a thousand is, that a patient comes or is sent to you, and the first and immediate object is the voluntary examination of that patient. Therefore, it may never enter into your head that there are cases occurring from time to time, more in the case of police surgeons, in which that same examination is not, or may not be, a voluntary one. And I shall have occasion to tell you of one or two cases which are nothing more or less than a medical scandal, which might have been avoided if the doctor had taken the trouble to think of these things.

From a practical point of view, you may put down as a synopsis of the classes of case or subject on which voluntary or involuntary examination may arise. The medical man acting in his private capacity, or a medical officer acting in his official capacity (the distinction is a very important one), may be called upon to examine:—

(1) An adult male or female capable of giving consent.

(2) A child under age.

(3) A person incapable, for other reasons than that of age, of giving valid consent. And such person may be (1) in the custody of the police, charged with an offence or crime; (2) not in custody, perhaps, or not even charged, but suspected by the police; (3) not in custody, nor even suspected by the police, but suspected or charged by other persons, such as a master or mistress. And, lastly, civil cases arising in Court, such as divorce, chastity, rape, etc.

There is an important principle which I want you to appreciate, because it holds throughout all Courts of Justice; it is, that no one can be compelled against his will to give evidence against himself. This principle has been carefully safeguarded even in recent legislation, in which the prisoner can appear in the box. It does not compel him to go there, nor permit any inference to be drawn from the fact that, through his counsel, he declines to do so. In all cases where examination of the person is desired, it is, or should be, so desired because evidence bearing on the case may be obtained from it. It is clear that until the examination has taken place, it is impossible to tell in which direction, for or against, the results may go. So by close logical reasoning we get the following general proposition, and this is an admitted principle of law: that such an examination can only be made with the consent of the person concerned. If made without his consent, it is technically an assault, possibly an aggravated or even an indecent one.

The second great principle, resulting from this is one which I do wish to emphasise most strongly, because in some of your cases in general practice you are apt to be misled, and put into a very false position through not remembering it. It is absolutely *ultra vires* for a policeman, a coroner, a lawyer, magistrate, or even judge, or Bench of judges, to make a *valid order* for the medical examination of anybody's person. *A fortiori* it is *ultra vires* for a master or mistress. And it is possible from decided cases and the dicta of judges, to lay down further propositions concerning consent, viz.: the consent must not be obtained by fraud, nor by any undue moral pressure, nor duress.

It must be freely given, after a full explanation of the circumstances for which it is asked, and of the consequences that may result from it. Silence here does *not* give consent, nor is compliance to be taken as consent. Moreover, where such consent can possibly be doubtful, it is well that it should be given in writing; and in all other cases it should be given in the presence of disinterested witnesses. Otherwise, there may be a difficulty in proving it. In the case of those who, from age or limits of understanding are incapable of giving valid consent, it must be obtained from a parent or guardian. And lastly, and by no means least, your own consent; ask yourself if there are strong grounds for believing an examination is necessary for clearing up points which are vital to the case. Could you make your grounds convincing to a jury if you were charged with assault? A jury is a very ticklish body, and you require to have some strong reasons for asking for this examination. Remember refusal to submit to an examination is not necessarily an admission of guilt. For instance, a prisoner may be suffering from venereal disease and be unwilling that the fact should be disclosed, and yet may be innocent of the crime with which he is charged. If the complainant has venereal disease, too, this coincidence may as likely be false or true. And we may certainly say that an innocent woman is just as likely, if not more so, to refuse consent than is one who is guilty. Conversely, you must remember that a desire to be examined must not be construed at once into a proof of innocence. Men who commit a crime like rape and unnatural offences are frequently well aware of the importance of an examination as *prima facie* evidence in their favour, should it be negative; and it is surprising how often a criminal assault has been committed without leaving any trace upon the accused, so that your results are likely enough to be negative, even in the presence of guilt. When consent has been obtained, let the examination in all cases, without exception, be made in the presence of a third party. Neglect of this precaution has ruined more than one medical man of good repute, when examining school children in the absence of a third party. Let us proceed to substantiate these principles by cases, decisions, and comments.

First, with regard to police surgeons, medical officers acting in an official capacity. They may be desired by police officers to examine persons in custody, or who are suspected by the police. Or sometimes they are asked simply to aid in detective work when one of several persons might be guilty. I shall read what is the law on the particular subject. It is from the Orders issued to the Metropolitan Police on the medical examination of prisoners:—

"The Law Officers of the Crown have advised the Secretary of State that it is expedient that a medical examination of persons charged with such offences as rape should be made (but note the following four words), 'when a prisoner consents.' The complete list of offences to which this is applicable includes rape and all offences under the Criminal Law Amendment Act, 1885, and all cases in which the examination under this Order without the prisoner's affirmative consent seems likely to furnish evidence as to the prisoner's guilt or innocence. If the prisoner consents to such examination he is to be told that if he desires the attendance of a qualified medical man on his behalf, an opportunity for such attendance with the

(a) Delivered at the Polytechnic, Chelsea Street, W.C., on Thursday October 28th, 1909.

Divisional Surgeon will be given, and arrangements are to be made accordingly. An entry is to be made, and signed by the Inspector at the time of every proposal for medical examination, and of the fact of consent or refusal being given by the prisoner in his presence; also of the offer made to the accused to allow a qualified medical man to attend on his behalf, and of the fact that the accused accepted or rejected such offer; and such entry should be read to the accused person. If an examination is made, and a committal for trial takes place, the officer must attend the trial, and prove the consent. The Divisional Surgeon must make a separate entry in his private memorandum book of any examination; and he must be informed of the time and place where his attendance will be required to give evidence before the magistrate. By an examination carefully conducted under these rules, the innocent man cannot suffer, and such examination will often furnish cogent evidence against the guilty. This order does not interfere with the accustomed police or other search of prisoners charged with felony."

Apparently the search of a prisoner's clothing is on a different footing to search of a prisoner's person.

I would draw your attention to the fact that consent alone is considered. Refusal stops the whole proceeding at once. He must not be told that if he refuses it will be put up against him. He who steps outside the four corners of this document does so at his peril.

I will relate a case to you. It is, in a sense, astounding, not only for the case itself, but for the action of the police surgeon. It occurred only this year, and I had it direct from the man who did it, and I told him he ought to be ashamed of himself. It happened in the North of London. A child was, apparently, born in the street, from one of two women who were passing along. The child was taken in by a passing Samaritan, as, of course, there was the usual crowd. The two women disappeared. Next morning the police visited the house into which the women had gone. They were attracted to that house by a trail of blood. But when the police reached that house the women had disappeared. The police next traced them to another house; they sent for the police surgeon, and, on entering the house, and finding the two women, they requested the police surgeon to examine one of them—the elder was beyond child-bearing age. She was told, "If you do not consent, I shall take you into custody." Of course, the officer who used that threat, whatever his rank, ought to have been discharged from the force at once, and probably he would be if the facts were known to the higher authorities. The police surgeon thereupon examined her, and found her to be *virgo intacta*." Obviously there was a trick played on the police. The child was simply dropped there with blood ready prepared, because they wanted to get rid of the child. My criticism on the case is that it is difficult to know who was most deserving of blame—the police or the police surgeon, because both were violating every principle of justice and mercy, and even decency, there being nothing but circumstantial evidence, which turned out to be absolutely misleading, to connect the woman with what, at its worst, was a mere doubtful crime—concealment of birth. That is a shocking illustration, and was really what led me to think I could do a little good by taking this subject for a lecture.

In the case of prisoners under arrest for a crime, it is to be admitted that there is no unanimity of opinion amongst the English judges as to the necessity of obtaining consent before examining a prisoner, and at a trial in 1890 for murder following rape, Baron Huddleston laid it down that the police had as good a right to examine a prisoner's person as his clothes. But most judges are of a different opinion, and medical men will act wisely in being on the safe side. Justice Hawkins, at the Central Criminal Court, in 1890, severely censured a divisional surgeon of police for not cautioning a prisoner as to the result of the examination. Police surgeons are but only to a very small extent covered by their lay officers. That is to say, if a police inspector assumes full responsibility

for the thing, you might bring a little pressure to bear on the woman, but I would still have it in writing, from a divisional police inspector, that he would be responsible for everything that followed. A warning is especially needed by medical practitioners called in by private individuals to examine a maid-servant or other woman. When a domestic servant is suspected of being pregnant, the mistress generally sends for her medical attendant to make an examination, so as to confirm or rebut the suspicion. Medical practitioners summoned for such a purpose should be careful to explain to the mistress that such examination can only take place with the free consent of the suspected servant, and that compliance does not mean consent. The servant should be kindly and gently told what is her mistress's fear, assured that the examination is suggested in her own interest, and to clear up a suspicion which may be ill-founded, and told plainly that it is for her to decide whether she will be examined or not. I can give you some details of a case of that sort.

The plaintiff was a woman, *æt.* 28, and was housemaid in the service of Captain and Mrs. Braddell. Some time before the occurrence the Captain and his wife had been from home. In consequence of some information given by a charwoman to Mrs. Braddell, the latter came to the conclusion that the maid was pregnant, and told her to pack up and leave before 12 o'clock, as she was in the family way. The plaintiff denied that she was, and the mistress said, "The doctor will be here presently." He had been sent for, and the mistress told the plaintiff to go to her room. She cried, and Mrs. Braddell forbade her to speak, and shortly afterwards the doctor came to the bedroom too. She said she had never had such treatment before, and asked him what he was going to do to her, and said she did not wish to be examined. There was some conflict of evidence between the plaintiff and the doctor as to whether she had consented or not, which might have been avoided had the examination taken place in the presence of a third person. He found there were no indications of pregnancy, but, notwithstanding this, Mrs. Braddell dismissed plaintiff, and refused to give her a character. So she brought an action against master, and mistress, and doctor. The jury did not agree, and they were discharged, and the case was re-tried before Mr. Justice Lindley, and a verdict was given for the doctor, more by luck than management. The case was not allowed to rest there; it was taken to a higher Court, and again the doctor got the verdict. Justice Lopez, a high official of the law, expressed himself in the following terms:—"He considered that sending for a doctor by a master or mistress, and directing him to examine a female servant without first apprising her, in any circumstances was an arbitrary and high-handed proceeding, and it could not, in his opinion, be justified unless the servant's consent be voluntarily given. The submission under the idea that she had to obey her mistress was not consent, and she swore at the trial that she did not consent." Lord Justice Brett went on and said:—"I cannot conclude this judgment without expressing my abhorrence of the whole conduct with regard to this unhappy girl from beginning to end. I cannot conceive how right-minded people could presume that a young girl is in the family way, that they should immediately take it into their heads that they are insulted. Why on earth should they have sent for the doctor? If they did not like to keep the girl, why not let her go away as quietly as possible? This idea of having servant girls examined by doctors is, to my mind, absolutely wrong, and it is conduct which everybody ought to scout."

In 1871 a case of alleged infanticide occurred which places this question in a very unhappy light. A young lady, sister of a clergyman, committed suicide rather than submit to an examination by two medical men under an order of the coroner. He was holding an inquest on a baby, and ordered the medical man to examine the woman. It shows how necessary was that broad statement which I made at the beginning. Here was a coroner who, examining into the death of a child, deliberately writes out an order for the examination of the possible mother. These two doctors,

armed with this order, went to the rectory where the lady was residing, requesting an interview to ascertain whether she had had a child, but she refused to see them, and subsequently destroyed herself. I think those medical men and the coroner ought to have been had up for manslaughter. Dr. Lowndes, of Liverpool, took legal opinion, and the barrister whose opinion he sought reports as follows:—"After diligent search on the coroner's authority, I have no doubt that physical examination of the woman in the case of suspected infanticide is grossly illegal. Such a method of obtaining evidence is against our principles of justice, and I can find no authority for it anywhere. The coroner issuing such order is liable to damages in action." He goes on to say that whether any, and if so, what change in the law on the present subject is desirable, is doubtful, but the matter will be a very hard one to settle. That was written in 1871, and one can see that the position is being somewhat altered. Our present Government, and the late one, are rather inclined by grandmotherly legislation to take more care of the individual than he will take care of himself, with the result that we get a lot of Acts of Parliament now passed which involve this question, I will not say of infanticide or examination in suspected pregnancy, but which involve the examination of patients. Take the Workmen's Compensation Act, for instance. Unless the workman chooses to consent to the examination, he may lose his compensation entirely. And it might, for that matter, be a woman who had been damaged, and unless she consents to the examination under such circumstances she may lose all her compensation. And the Children Act of 1908, and all the various Acts under which school children are being examined, are illustrations of the fact that Parliament is rather assuming the right to insist upon examinations; but, until Parliament has acted, let me strongly advise you to be very careful what you do about examining anybody. There is another aspect of this infanticide question. A woman may consent to be examined, and it may be that the question of recent delivery arises. It may be known for a certainty that she had had a child, and she may admit that she destroyed it. *Per contra*, she may deny that she ever had one, and then you have to consider all the signs of delivery at more or less remote periods, and, as Dr. Taylor put it, it is just possible that examination of the dimensions of the pelvis might be necessary, because there may be a defence raised of protracted delivery, and consequently of dead birth. What I am chiefly concerned with now is to warn you against examination unless you have full consent.

Let us now take the case of males charged with rape and indecent assault. In the notorious case of "Bolton v. Parke," a London police surgeon received a rebuke from Lord Chief Justice Cockburn for having examined one of the accused without having first obtained his consent. The Judge told the prisoner he would have been justified in knocking him down. Dr. Lowndes, of Liverpool, says:—"Within the last twelve years I have been frequently asked to examine male prisoners charged with rape and indecent assaults. I have not only always made it a rule to obtain their free consent, but have added this caution: 'The result of this examination may be in your favour or it may be against you. In either case I shall be obliged to tell the truth. Do you still consent?' If the patient consents, and proceeds to undress himself, I have no hesitation in examining him."

Take the case of a man who had at the time a Hunterian chancre, and the girl upon whom he was charged with committing a rape was suffering from syphilis. Syphilis is extremely common, and the fact that a man charged with rape had syphilis is nothing extraordinary. So it is merely circumstantial evidence of very doubtful value. Many of these men know when they are in custody that the police surgeon will very likely appeal to be allowed to examine them; some of them will ask for examination. A man with gonorrhoea will deliberately pass his water about an hour before he knows an examination will occur, and so apparently free himself from any appearance of having gonorrhoea. If he has committed rape he may deliberately wash himself. This happened in the case of a collier who was charged with committing a rape; and he insisted upon being examined, and at the exam-

ination the only part of him which was found clean was his genitals—his legs were still black with coal. He was, of course, asked why he had washed his genitals, and those only.

#### EXAMINATION OF THE DEAD.

With regard to the performing of a post-mortem examination on a person, the law is that nothing further than the written order of a coroner is required, or, in non-judicial cases, the permission of the nearest relative or guardian. On the question of possession of a dead body, no property resides in a dead body, and, should a post-mortem be done without consent, no offence at law is, *ipso facto*, committed; it is only a moral offence against the relatives, which, of course, should be avoided. Removal and preservation of organs is no offence. One or two actions are on record of living persons claiming, by legal process, portions of their anatomy, and judgment has always been entered for the plaintiff.

If a patient dies, and you think you would like a post-mortem, there comes the reasons why you would like the post-mortem. I have put them down into four categories:—

(1) If it is obvious that the cause of death is a natural one, and the doctor wants a post-mortem for his own ends, the consent of a responsible relative or guardian must be obtained. If another relative objects, the medical man would act wisely by desisting. If he persists when there is objection, he is acting illegally when he forces access to the body against the authority of the master of the house wherein the body lies. The post-mortem examination itself is not illegal under these or any such circumstances.

(2) The second group is, that where the cause of death is doubtfully natural, and the medical man cannot clear it up without an autopsy. One of three courses is open to him: (a) The most unsatisfactory, but, withal, one which is often pursued: to swallow objections, and sign a certificate on a simple disease, and omit any mention of accident or foul play. Rumours in such a case may spread, all sorts of questions may be asked, and the medical man may be severely handled; (b) The second course is to explain fully to the responsible person the need for an autopsy, and obtain permission to perform it. He is fully entitled to perform it, because he is as yet uncertain whether an inquest will be necessary. If he has made the autopsy under these conditions, he must not suppress any facts which he has acquired. If he finds any evidence of unnatural death, he is bound to report the matter to the coroner. If, with the cause of death unknown, he is refused a post-mortem, he must report the matter to the coroner, and refuse to give a certificate. If once circumstances have arisen, whether before or after death, which necessitate report to the coroner, the medical man must on no account touch the body for the purposes of an autopsy without the written authority of the coroner. To do so without such authority is to render himself liable to be committed for contempt of Court. In 1904, a doctor named Carlton was summoned under the old Anatomy Act of 1832, for performing a post-mortem without permission. As a matter of fact his prosecutors found it was no good proceeding with the matter, that no jury would convict. The ground of their action was, that he, being a person lawfully qualified, did practise anatomy without having obtained a licence under that old Anatomy Act. So by performing a post-mortem in any case you are not committing an illegal act; you are not assaulting anybody. There is no property in a dead body, except on the part of the nearest relative, and it is only their property in so far as they must dispose of it without being a nuisance to their neighbours.

I trust now, gentlemen, that you will not go examining prisoners without their consent, and be very cautious about what you mean by "consent."

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by John Bland-Sutton, F.R.C.S. Eng., Surgeon to the Middlesex Hospital. Subject: "On Appendicitis when the Vermiform Appendix is a Pelvic Organ."

## ORIGINAL PAPERS.

## THE STUDY AND TREATMENT OF ACUTE PERITONITIS. (a)

By PROFESSOR FEDERMANN, M.D.,

Of Berlin.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

## PART II.

## TREATMENT.

GENTLEMEN,—If I now summarise all that has been said, and pass on to the treatment of peritonitis, it can scarcely be doubtful to you that a rational treatment of peritonitis can only be an operative one. With the present state of our scientific knowledge, we cannot expect to materially influence the infective process. If spontaneous recovery from a case of peritonitis takes place, the cause thereof lies in the favourable relationship between the infection and the resisting powers of the individual. Our internal measures can only at present obviate certain mischiefs and support the organism. In all severe cases of peritonitis this does not suffice. Up to now even serum treatment makes no exception to this.

The chances of operative procedures, however, are only favourable when they are carried out at a proper time, *i.e.*, in the early stage of the disease. Early operation is the greatest step in advance in the whole question of peritonitis. What do we mean now by early stage and early operation? There is still a great deal of uncertainty in regard to these two questions. This depends on the fact that there is at present no exact definition of this epoch of the disease, neither for any individual form of the disease, still less as regards peritonitis as a whole. The early stage sometimes passes unnoticed, sometimes with violence into the intermediary stage, or, in the grave perforative form, direct into the last stage. As we cannot define it distinctly, either anatomically or clinically, only a biological definition is appropriate that best hits the centre point of the matter. We can say that a peritonitis is in its early stage so long as the resisting power of the organism has not passed beyond certain limits. In practice we must always bear in mind that the duration of the early stage must always vary according to the severity of the infection, and that it lasts the shorter time the severer the infection, and the longer the milder it is. Thus in a case of perforation of the stomach the early stage has passed within twelve hours, whilst in a case of appendicitis of medium severity early operation may be performed on the third day with good chance of success. In general I might take 36 hours after the commencement of the first marked signs of the disease as the highest limit, at least for the majority of cases, at which an operation may be carried out with any probability of success, but I would emphasise that in a class of cases—and above all in perforations of the stomach and intestines—the operation must be done within the first 12 hours. Otherwise it can only be done in the presence of severe complications, or we come too late altogether. It will be understood that the above will be demanded only when the histories are very exact, above all in little children in whom, as experience has shown, often only a very slight illness means the commencement of an attack of peritonitis.

If we are in the fortunate position of being able to operate in the early stage of an attack, the chances are excellent, and from that point of view the operation is one of the most satisfactory in the domain of surgery. Whoever has been present at an early operation and has seen how a condition dangerous to life has been changed at a stroke by a rapid and slight procedure, will agree with me in feeling convinced that our mode of treatment has been the correct one, and will be satisfied with it.

Operation in the early stage has essentially two demands to fulfil: to do away with the point of origin of the infection, therefore to remove a diseased

organ or to close up the opening of a perforation; and, secondly, to clear away any exudation that may be poured out, and by conducting it permanently outside prevent the further absorption of poisonous material into the blood. We can accomplish both these aims in a manner simple, sparing to the patient, and without danger. Extensive incisions and counter openings are superfluous; the incision may be closed up to a small opening for a drain. The operation is without danger itself, as the resisting powers of the patient have not been weakened, that of the peritoneum has been enormously increased, so that infection of the healthy peritoneum rarely occurs, or is easily overcome. In this lies the secret of the success of early operation. For this reason it must be emphasised again and again that the diagnosis must be made within this limit of time, and we must not rest before then.

But it is not every case of peritonitis that requires operation in the early stage. Under all circumstances it is indicated in all cases of perforation, whether of the stomach, intestines, or any other organ. True perforative peritonitis only very exceptionally leads to circumscription, and without operation goes on rapidly to death. And withal the early stage passes so immediately into the later one, with its most unfavourable prognosis, that we cannot operate early enough if we would obtain favourable results. How often have I seen a perforation of the stomach in a hopeless condition even within 12 hours! I need not express myself as to the characters of a case of perforation in the later stage, nor tell you that it is always hopeless. Prostration, extinction of all reactive expressions is its sign. Low temperature, disappearing leucocytosis, small galloping pulse, meteorism from paralysis of intestines, uncontrollable vomiting, a feeling of euphoria, leave no doubt as to the diagnosis and prognosis. Exceptionally, operation still helps; the organism succumbs to the poison so freely absorbed. May we never allow it to get to that stage.

In diffuse gonorrhœal peritonitis early operation is unnecessary, as I have frequently observed, as it is capable of spontaneous recovery (Barth, Martin, Fowler). But the recognition of it is not easy, as it has a stormy onset with severe symptoms. If there is a suspicion, but without certainty, that a case is of gonorrhœal origin, a diagnosis must be made by exploratory puncture through the posterior vaginal arch. A quickly made dry preparation shows the presence of gonococci, or their absence.

Amongst the forms of peritonitis appendicitis takes a special place, which receives its peculiar and special stamp from participation on the part of the peritoneum. For this reason it is deserving of particular mention, as in it the accompanying peritonitis is of all kinds, from the simple fibrinous to peritoneal sepsis. We distinguish only an appendicitis simplex, without participation in the peritoneum, or with sero-fibrinous peritonitis, and appendicitis destructiva (gangrenous, perforating) with purulent peritonitis. These two groups can almost always be diagnosed and kept apart, from the clinical symptoms. In simple appendicitis the pain on pressure is almost always limited to the right side; the number of leucocytes does not exceed 15,000. All the symptoms are moderate in degree, and distinctly recede, even after 24 hours. In simple appendicitis I consider a waiting attitude to be justifiable, and early operation to be unnecessary, as the affection soon subsides spontaneously. I well know that a simple appendicitis can change about suddenly, but on the one hand, according to my own experience, this is an extremely rare occurrence—for the most part the case has not been observed properly—on the other these cases should decide us to watch even the mildest attacks with great attention, so that we can operate on any unfavourable turn.

Destructive appendicitis, however, with purulent peritonitis, at the bottom of which there is always either gangrene or perforation of the appendix, should always be operated on within the first 36 hours; that is, treated like any other peritonitis. The clinical symptoms correspond to those already described, and may almost always be distinguished from those of

(a) An Address delivered before the Charlottenburger Aerzteverein.

simple appendicitis. In destructive appendicitis the peritonitis is always diffuse from the first, and we can never say with certainty beforehand whether or nor encapsulation will take place. For this reason we should not wait and put off the favourable moment for operating. Even in those cases that proceed to abscess formation secondarily, there is no object in waiting for this event, nothing is gained, and time and strength are thrown away. Early operation in which the small incision can be almost closed by suture, is better than a big, objectionable incision into an abscess. We shall not go out of our way to decide whether the peritonitis will become encapsulated in a case of appendicitis; such a decision is almost impossible at the commencement, and it is also of no importance, but limit ourselves to separating the two chief groups, which is almost always practicable. And if at last we lean to the radical side, operate in doubtful situations, when only one symptom is present that causes anxiety, in my opinion—and in that of many surgeons—a practical position will have been taken up as regards the treatment of acute appendicitis.

But however agreeable it would be to get all cases of appendicitis in hand within the first 36 hours, in practice this ideal is hardly within reach, in a great town; at present we see quite enough cases that have been ill three and even four days, or even more. The conditions these cases present are quite different from those in the early stage, and as you know essentially worse. The operative mortality in appendicitis from the second to the third day rises from 4 to 40 per cent. However, we must take the cases as they come, and endeavour to find a therapeutical standpoint, even as regards the late ones. There are cases of appendicitis that are in the last stage even on the third or fourth day, where all treatment is useless; but it is not these cases that I have in my eye. They are lost, and the kind of treatment is a matter of indifference. But there are cases of medium severity with the peritonitis progressing slowly (at an earlier stage progredient fibrino-purulent peritonitis) that do not pass immediately from the first into the final stage, but run a middle course, that has been called the intermediary stage. This so-called intermediary stage is only met with in appendicitis; its duration varies with the severity of the case; it may under certain circumstances last for a week. The anatomical condition is a varying one, but there is always a diffuse purulent exudation of various extent, with soft adhesions. Clinically, these cases are distinguished by the excessive diffuse meteorism from paralysis of the intestines, with diffuse tenderness on pressure. There is no circumscribed resistance. The general symptoms, pulse, temperature, leucocytosis, are all thoroughly typical. The organism is in such exact equilibrium that the slightest weight on one side or the other will pull that scale down. The end is either circumscription, *i.e.*, an abscess forms, when the patient is generally saved, or the peritonitis progresses unrestrained till death takes place.

How shall we act in such cases? I can indeed say that the decision in such cases forms one of the most responsible and difficult questions in the whole domain of the treatment of peritonitis, and that every symptom must be again and again compared and carefully weighed. If any resistance is perceptible the case decides itself, and we must wait until the limitation becomes definite. But in the typical cases there is no resistance. Shall we here operate at once so as to bring the disease to a standstill, or shall we wait in the hope that the diffuse inflammation will proceed to localisation? There are surgeons who operate in all such cases in this stage; the majority do not, they treat the cases individually. In my experience many a case has fallen a victim to operation, as the operation is no longer free from injury and danger, as it was in the first 48 hours.

If a comparison of all the symptoms—particularly the character of the pulse—gives a satisfactory picture of the state of the system, this is mostly incomplete as a guide for operative procedures. There is no sharp reaction that will enable us to judge of the patient's

resisting power, and so of the prognosis. I believe, however, that we have in the examination of the blood a means of filling up this gap. So long as the number of leucocytes is still high, 20,000 or over, it is proof that the resisting power is still sufficient, and therefore favourable in view of operation. All the cases that I have operated on in the intermediary stage, when the leucocytosis has been high, have recovered—naturally with complications quite often. But if on the third day or later we find a low leucocytosis, 15,000 or under, I take it that operation is contra-indicated for the moment, as the patient's powers have become so exhausted that operation will only hasten the end. I have never seen a case of purulent peritonitis operated on with a low or falling leucocytosis that recovered—whether the vermiform appendix was removed or not. In these cases we must rather endeavour so to raise the resisting power of the organism that the disease may become circumscribed. The best means for this are permanent infusions of saline solution into the rectum, several litres a day; they are well borne, and they are an excellent reinforcement for combating the infection. Opium should be rejected, as it checks peristalsis and masks symptoms. I know a number of cases in which there was apparently no prospect whatever of recovery, in which under this treatment the disease became localised, the leucocytosis improved, and an abscess formed that was incised. Recovery is almost assured by this. I might permit myself here to show a typical cure of such a case that came under treatment in a desperate condition, with a leucocytosis of 13,000, and general meteorism. Not until the eleventh day was there any distinct resistance in the upper part of the abdomen—a certain sign that there had been general diffuse inflammation—it became larger, and on the thirteenth day an incision was made into an abscess the size of an apple, with recovery.

If an abscess is distinctly to be felt—and it will be found above all in Douglas's pouch—it should be opened: the appendix is, however, not removable as a rule, as an opening into the free peritoneum must be looked on as highly dangerous at this stage. In a number of cases that under operation would offer a very unfavourable prognosis, the disease may be arrested, and limitation and recovery led up to. This is especially to be emphasised as regards those who desire to operate on every case in this stage.

Gentlemen, I am at the end of my task, and I am well conscious how many gaps there are in what I have offered you in this interesting and important subject—in the still numerous questions to be solved. The short hour that was at my disposal explains this. I intended to draw you a picture of the development of peritoneal inflammation, how in its principal features it runs the same course in all forms, and to show you that we can only then have certain successes, when we recognise the disease in all its stages—and above all in the very first—and are in a position to judge of its importance—its dignity (Dignität). Only the careful collaboration of internists and surgeons will be able to reduce the mortality of the disease to a minimum. The general practitioner sees the patient first, and in his hands, in the first instance, lies the fate of the patient.

## THE TEACHING OF PRACTICAL MIDWIFERY IN THE PAST AND AT THE PRESENT TIME. (a)

By HENRY JELLET, M.D., F.R.C.P.I.,

King's Professor of Midwifery in the School of Physic, Trinity College, Dublin; Gynaecologist to Sir Patrick Dun's Hospital, Dublin.

THE subject which I have selected as the basis of my introductory address is one which has been prominently before the various bodies interested in medical education during the past couple of years, and which has also been the subject of an important debate in this Section of the Academy. I propose to refer to the official regulations which have existed for the teaching of practical midwifery in the past and in the future. The members of this Section labour under no delusions as to the importance of this subject. They see daily both in their hospital and in their private practice the results of its neglect in the past, and many of them have worked hard to effect improvement. It is only too obvious, however, that the bulk of what may be called the governing bodies of the medical profession have taken a long time to appreciate the needs of, and for, a thorough practical education in midwifery and gynaecology, and though that lack of appreciation was more marked in the past—as I think my address will show—it is still existent. So far as my own experience goes it seems to me that gynaecologists and obstetricians are able to take a broader and saner view of the relative importance of subjects in the medical curriculum with which they are not personally concerned, than is the physician or the surgeon. It is only a short time ago that, during a discussion on the teaching of midwifery, a prominent medical man decried the necessity for improving it, and pointed out that already more time was devoted to the teaching of it than to the teaching of diseases of the eye, while, said he, all humanity have two eyes, whereas only a part of it has one uterus. Nor was he willing to accept the fact that the general practitioner—for one eye case which he meets which cannot wait for the services of a specialist—meets, I suppose, twenty cases of labour, whose safety and future welfare are entirely in his hands.

It may be said that this is only the special pleading of a specialist for his own speciality. But what specialist has ever yet advocated the extension of obstetrical and gynaecological teaching beyond the degree required by the general practitioner? All our complaints have been directed against the fact that, while it is the object of all medical education to turn out not specialists but general practitioners, education in one of the most important branches of general practice was neglected and almost reduced to a farce. It is not so long since the General Medical Council considered it sufficient education in practical obstetrics if a student attended twelve cases of labour, of which he was to conduct three personally under the supervision of any registered medical practitioner. When efforts at reform were made, the upholders of such a system openly expressed the view that the student as regards midwifery must obtain experience after qualifying "in the same manner as he does in respect of medicine and surgery." If the subject of midwifery was comparable in its extent with a single disease, such for instance as typhoid fever, then the argument might have some weight, since students must perforce go out with only a scanty practical knowledge of individual diseases and acquire a fuller knowledge later. But can such a comparison be made? Is it not more correct to compare midwifery with a group of diseases, such for example as the diseases of the thorax, and what clinical teacher would suggest that it was sufficient for a student to examine three cases of thoracic disease in order to acquire a general practitioner's necessary knowledge?

In the Spring of 1888 the General Medical Council

(a) Presidential Address delivered at the Opening Meeting of the Obstetrical Section of the Royal Academy of Medicine in Ireland, Nov. 5th, 1909.

received a report from their Education Committee, and one part of this dealt with "the importance of increased attention to general and special clinical work." We are only concerned with one of the several recommendations brought forward by the Committee, and this was to the following effect:—

"That every student should be required either to attend for three months the indoor practice of a lying-in hospital, or to have been present at not less than twelve labours, at least three of which he should have conducted personally under the direct supervision of a registered practitioner." An amendment to the effect that the number of labours to be attended by the student should be increased from twelve to twenty was rejected, and the recommendation of the Committee was adopted, thus rendering it possible for a student to be qualified to practice midwifery after he had personally conducted three cases of labour under the supervision of any medical practitioner.

In 1891 the teaching of midwifery again came before the General Medical Council as a result of a motion moved by Dr. Glover, and seconded by Dr. Athill, to the following effect:—

"That it is urgently necessary for the examining bodies to require of candidates for their diploma additional guarantees of their practical education in obstetrics; and that candidates at the final examination be required to produce proofs that they have personally conducted at least six, and have been present at at least twenty-four additional labours, or of having attended as pupils for six months a lying-in hospital, or the lying-in department of a general hospital, or a maternity institution, with arrangements for clinical teaching approved by the examining body granting the diploma."

This very moderate proposal was defeated by an amendment which whittled it down a little, only to be itself defeated by another which still further reduced it. Finally, the opponents of any reform considered they were sufficiently strong to move that the Council resolve to adhere to its existing resolution, and this was carried, and the *status quo* maintained.

In the winter session of 1895, the General Medical Council received a petition from the Council of the British Medical Association to the effect that the members of the Association viewed with deep concern and regret the admission of students to their final examination after they had personally conducted only three and been present at only nine confinements. The Council of the Association therefore petitioned the General Medical Council to recommend that no student be admitted to his final examination until he proves that he has personally conducted at least thirty confinements under the direct supervision of a medical practitioner. This proposal removed some of the farcical elements of the existing state of affairs, but, inasmuch as it recognised any general medical practitioner as a suitable person to teach practical obstetrics, it would have failed in its object. The petition was received by the General Medical Council, and referred to the Education Committee for consideration and report, a step which was at least a recognition that the existing state of affairs was not perfect, and so was a great advance on the action of the Council in 1891.

The Education Committee, so far as one can judge from the report presented to the Council, gave the matter a very careful consideration, and, though it is impossible to recognise their resultant recommendation as anything but insufficient, it is evident that they had to contend against very serious opposition to any step for the improvement of midwifery teaching. The inevitable compromise resulted, and while students were to be allowed to put in a three months' attendance at a midwifery hospital if they wished, they were also to be admitted to examination after being present at not less than twenty labours, at least five of which were to be personally conducted under the direct supervision of a registered medical practitioner. This recommendation was adopted by the Council, and remained as their recommendation to the licensing bodies until the adoption in 1907 of

the series of resolutions to which I shall now refer, and which signalled the advent of an entirely new system in the teaching of practical midwifery.

At the May meeting of the Council in 1905, on the proposal of Sir John Williams, it was resolved to appoint a Committee of the Council to inquire into the operation of the rules regarding the midwifery practice required of candidates for medical qualifications. This reference covered a wider field than any previous reference made to any Committee appointed to inquire into the teaching of practical midwifery. The Committee, which had reported in 1895, had been limited in its scope to inquiry into the attendance by the student on cases of labour under the supervision of a medical practitioner. The reference to the present Committee covered the whole teaching of practical midwifery.

With the object of obtaining information on the subject a series of questions were sent by the Committee to "the licensing bodies, which include teaching institutions, and to other teaching institutions which are recognised by the licensing bodies for subjects other than those of the first year's course." In this respect I think that so far as Ireland, at any rate, was concerned a mistake was made, inasmuch as many of the questions asked came within the purview of the teaching midwifery hospitals rather than of the licensing bodies, who were unable to answer several of the most important. It is impossible here to enter into the different questions asked, but one question and its answers may be mentioned:—

Question.—What proportion of your students "attend for three months the indoor practice of a lying-in hospital" as an alternative to not less than twenty cases of labour?

Summary of the answers received from 37 institutions.—In eleven schools none of the students attends for three months the indoor practice of a lying-in hospital "as an alternative to twenty cases of labour"; and of those in ten others practically none does so. About 50 per cent. of the students in one school take the alternative. Almost all the students in six schools take the three months hospital course.

So far as I can judge from a perusal of the replies received by the Committee, the taking of a hospital course was a matter of the greatest rarity in any but in the six schools last mentioned, and, in almost all the others, students acquired their knowledge of obstetrics by being present in fact, or in theory, at twenty cases of labour of which they personally conducted five under the supervision of a general practitioner. Further it appears, and the Committee in their report emphasise the fact, that in the majority of schools even the minimum requirements of the Council were not complied with. It is no wonder then that the Committee went on to report that "it seems obvious that, even if the course of study recommended were in itself sufficient, since its requirements are not complied with, there is no evidence to show that persons obtaining qualifications possess the required knowledge and skill for the efficient practice of midwifery."

The recommendations of the Committee were subsequently twice altered before their final adoption, and so I do not quote them in full. They laid down for the first time three important principles which persist in those finally adopted. These were—

(1) That the student must have received adequate instruction in medicine, surgery and midwifery before beginning the study of practical midwifery.

(2) That he must have attended the indoor practice of a lying-in hospital or of a general hospital or poor-law infirmary having lying-in wards, before he is permitted to conduct extern cases.

(3) That the certificate showing that he has conducted the necessary number of cases must be signed by a member of the staff of one of the institutions mentioned in (2), thus doing away once and for all with the system of fortuitous instruction by any general practitioner who might or might not be suited to impart it.

This report came in May, 1906, before the General Council, who ordered it to be sent to all the licensing bodies and teaching institutions, inviting criticism

thereon. The criticisms received were then considered by the Committee, and, as a result, certain minor changes were made in their recommendations. The consideration of the Committee's report by the Council was, however, postponed in order to give various bodies which had not already replied an opportunity of doing so, and, in consequence of these replies, some further alterations were made in the recommendations. Finally, in May, 1907, the General Council adopted, almost unchanged, the recommendations of the Committee, with the result that, on paper at all events, a very definite and practical effort was made radically to improve the teaching of practical obstetrics.

I trust I have not wearied the Section by this dry *présis* of the past history of the teaching of practical midwifery. If I have not, I should now like to say a few words on the probable effect of the recommendations of the General Medical Council on the future of such teaching. The recommendations of the Council are only recommendations, and, as such, can be ignored in part or in whole by the licensing bodies. Some idea as to the probable attitude of the latter can be gleaned from their criticisms of the first Report of the Practical Midwifery Committee of the General Medical Council, and in these criticisms there is manifest an extraordinary divergence of opinion. The majority of the London Medical Schools consider it quite impracticable to insist on regular attendance upon the indoor practice of a lying-in hospital. The majority of the Scottish licensing bodies, and of the English Universities, and all the Irish bodies, view the proposal with approval. The University of Manchester expresses "unqualified approval of the recommendation that certificates of attendance on labour shall be accepted only from a member of the staff of a public lying-in hospital, or of the maternity charity of a general hospital." The University of Birmingham considers that "general practitioners should not be altogether excluded." The Professor of Midwifery at Bristol University College considers "that practitioners who have received their education in lying-in hospitals only are not so reliable as those who have been taught in an extern maternity." The Professor of Midwifery in St. Mungo's College, Glasgow, is "of opinion that a student will learn more by attending in the wards of a hospital and seeing cases properly conducted than by attending scores of cases in their own homes." These are only a few instances taken at random, but they serve to show the differences that exist. It is probable—indeed, almost certain—that the large Universities whose supply of students is constant and independent of minor alterations in the curriculum, will adopt the recommendations of the Council in their entirety, while licensing bodies who are, so to speak, competing against one another for students, will endeavour to present their curriculum in as attractive a form as possible. Similarly, the schools which consider the recommendations impracticable will doubtless continue to do so, until the licensing bodies, to which the schools act as feeders, demonstrate their practicability by making them essential.

Here, in Ireland, we are principally concerned with the actions of the Irish Universities and licensing bodies, and, so far as I am aware, the Conjoint Board of the Royal Colleges have so far alone modified their regulations. Their alterations are thus of considerable interest as foreshadowing to some extent the possible action of other bodies.

Before referring to them, it is necessary to state that for many years past in Ireland the regulations for the teaching of practical midwifery have been sufficient, if the student chooses to benefit by them. Instead of its being possible to become qualified after seeing 20 cases of labour and conducting 5, the Irish student had to attend for six months in a maternity hospital, and to conduct some 20 cases. I emphasise this point because there is a danger present that the efforts of the General Medical Council to produce a leavening up of midwifery teaching in England and Scotland may result in producing a leavening down in Ireland, and, indeed, we shall see that, in the case of the Irish Colleges, already it has been decided to reduce the

course in a maternity hospital from six to three months in order to bring it into closer conformity with the recommendations of the Council.

The regulations of the Colleges, which have been agreed on after a prolonged discussion, and which will shortly come into force, are as follows:—

(1) Every student before beginning the study of practical midwifery must have attended a course of lectures on midwifery, and must have held the offices of clinical medical clerk and of surgical dresser.

(2) Every student must attend the indoor practice of a lying-in hospital, or the lying-in wards of a general hospital, for a period of three months, to the satisfaction of the medical officer in charge, and, after having received therein practical instruction in the conduct of labour under the personal supervision of a medical officer, must attend twelve cases of labour under official medical supervision.

(3) Every student must attend on at least thirty-two occasions on the regular clinical instruction delivered in the wards of a lying-in hospital, or in the lying-in wards of a general hospital.

(4) All certificates testifying that the student has complied with the above regulations must be signed by a medical member of the staff of a lying-in hospital, or by a medical member of the staff responsible for the management of the maternity wards of a general hospital.

The foregoing regulations are admirable in many respects, but in one particular they are retrograde. It was unwise from every point of view to reduce the course of hospital teaching from six to three months. It was unwise from the point of view of the student's education, because a three months' period is insufficient, and it was unwise from the point of view of his comfort, because it would be easier for him to obtain the necessary number of cases and the necessary hospital attendance in a period of six than in one of three months. On the other hand, it is most important to have obtained a definite pronouncement that the student must attend at the regular clinical instruction delivered in the wards of a hospital.

What the action of the other Irish licensing bodies may be remains to be seen. I trust that it will be in the direction indicated by the regulations of the Royal Colleges, but that there will be no shortening of the periods of hospital attendance. It is for the Irish school to improve and to increase its present standard, and not to let itself forget that what may be improvement in other teaching centres may be retrogression in Ireland.

There is just one other point to which I wish to refer before I finish. The General Medical Council, in their final recommendation to the licensing bodies, added to the recommendations already mentioned another to the effect that it is necessary for the licensing bodies "in the public interest" to establish clinical and practical examinations in midwifery and gynecology in connection with the qualifying examinations. At first there was considerable uncertainty as to the practicability of such a scheme, but when it was examined closer it was found to be quite workable. Trinity College and the Royal Colleges have already adopted it, and in future all their students will have to present themselves for such an examination. Its value, if it is properly carried out, is undeniable, and it remains with the examiners to see that the examination is a reality.

If we contrast the present state of affairs with what existed in 1888, we shall see what a great advance there has been in the teaching of practical midwifery, and this Section of the Academy, as a Section, and many of its members individually, have had a large share in this. In 1888, it was impossible for any student, who merely followed official requirements, to acquire a sufficient knowledge of obstetrics before he was qualified to enable him to undertake the care of the average case of labour. At present, under the new regulations, it is possible for most students to obtain the necessary knowledge. It must be the object of the future to ensure that it is impossible for him to become qualified without such knowledge.

## ON SOME RELATIONS OF PHYSIC TO PHYSICS, AND THEIR BEARING UPON THERAPEUTICS. (a)

By WALTER G. SMITH, M.D.,

Ex-President of the Royal College of Physicians of Ireland.

IN the desultory remarks which I offer to you this evening, I will assume that the term physics includes chemistry. For it is evident that physics, no longer content with the molecule, has now annexed the sacred atom of the chemist.

The atomic theory has scarcely passed its centenary, and yet we have already become familiar with phenomena which prove that the immutable and indivisible atom of the nineteenth century has lost these attributes. Chemistry, while its ordinary practical course is untouched by the new revelations, has come to recognise that the atom is a microcosm in structure, and conceals an amazing storehouse of energy, electrical in its nature.

In the early dawn of medicine, theology and therapeutics—the former spelt with a big T—were closely interwoven. By degrees the ill-assorted alliance has been severed, and, in later days, all earnest cultivators of medical science have done their best to emancipate it from the thrall of superstition and of mere dogmatic authority.

This is the true Renaissance of Medicine, and the spirit of free inquiry, or moderate doubt, is the distinctive feature of modern thought. We can the more truly reverence the great fathers of medicine, Hippocrates and Galen, although we do not bow down and worship them as was done for many centuries. In our own times we witness the rash endeavours of certain clerics, in America and elsewhere, to re-engage in practical therapeutics, and, with the self-assurance born of ignorance and conceit, they intrude where they ought not, and meddle where they can do nought but mischief. As Osler ("The Treatment of Disease," *Brit. Med. Journ.*, July 24th, 1909) aptly quotes from Fuller:—"Circe and Æsculapius were brother and sister, and the wiles of the one are very apt to entrap the wisdom of the other."

Homœopathy had for a time a sickly existence, and has nearly perished of inanition. But its vacant throne is, in part, occupied by that audacious fraud and moral influenza, yclept Christian Science, a pursuit the "Christianity" of which is as *bizarre* as its "science" is contemptible. A woman lately died at Worthing who had been suffering from consumption for five years. At the inquest it was stated that she had been in the hands of Christian Scientists, who charged her a reduced fee of five shillings weekly for praying twice daily. The regular fee was £1 1s. (*Irish Times*, September 14th, 1909.) To Christian Science may be fitly applied a "bull" once perpetrated in the House of Commons—"It is a lie, sir, and it is high time we nailed this lie to the mast."

It might be supposed that, with the advance and spread of scientific knowledge, quackery and superstition would die out. Yet the experience of the ages teaches that man has an ineradicable hankering after the unknown and the unknowable, and is ever ready to pin his blind faith to the incredible and the marvellous.

Man is, by nature, an idolater, and he revels in that greatest of all human capacities—the capacity for self-deception (Osler).

While we gladly allow that chemistry has made magnificent contributions to our stock of remedies, the very facility with which organic syntheses can be effected has its disadvantages.

Of the innumerable new remedies which are daily showered upon us, most of them are like falling stars which flash across our path for a moment, and leave behind not even a speck of therapeutic dust. A few, like meteorites, cling to earth and become part of our possessions.

We are ready also to admit our obligations to the pharmaceutical skill of the great drug firms, but they now presume, under an ill-disguised humility, to teach us our business, and, by their commercial wits, they

(a) Presidential Address at the Opening Meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland, October 29th 1909.

batten upon the witlessness of the public—lay and medical.

They invade us in our consulting hours at home, and bombard us with their pseudo-scientific missiles—heralded by a flourish of fearful chemical formulae, and so degrade the progress of real therapeutics to a vulgar commercial competition.

"Where is boasting, then? It is excluded."

Let us turn now to other thoughts.

An analogy may be traced between the parallel courses of modern physiology and modern chemistry.

For a time the investigations of physiologists ran largely on systems and tissues; those of chemists on systems, groups, and types. During recent years the tendency in each is to return to the closer study of their respective units. That is to say, the cell for physiology, the atom for chemistry and physics. In each case the unit turns out to be a highly complex structure, with infinite potentialities, and the atomic hypothesis plays the leading part in the physical science of to-day.

The two great laws which serve as beacon lights in the investigation of natural phenomena are the generalisations known as the laws of thermodynamics—

(a) The principle of conservation of energy—the first law.

(b) The doctrine of the transformations, or degradation of energy—the second law of thermodynamics.

These two principles are obeyed throughout the whole range of organised Nature, and, as Benjamin Moore shows so clearly in his interesting and suggestive articles in "Recent Advances in Physiology and Biochemistry," the living cell is an energy machine or transformer.

To comprehend and follow these exchanges of energy is largely, for biologists, the task of the new branch of study termed physical chemistry, which may be regarded as the product of the cross-fertilisation of physics and chemistry.

So far as we can ever hope to penetrate the mystery of life, it is surely only by the aid of such inquiries and experiments. This was dimly perceived and felt by the older seekers after truth, as is seen in the gropings of iatro-mechanics and iatro-chemistry in the seventeenth and eighteenth centuries.

Methods of physico-chemical therapeutics—e.g., massage and hydrotherapeutics—reach back to antiquity, and one of the earliest recorded examples of hydrotherapeutics is related in the story of the cleansing of Naaman's "leprosy."

In my address to this Section last year upon "Baths and Mineral Waters," I attempted a brief and inadequate sketch of the physico-chemical principles which lie at the foundation of scientific balneology. If we were to take seriously the claims of the proprietors of the different mineral waters, they would have us to believe that each spring is a veritable pool of Bethesda. But the pool needs to be stirred with the rod of science.

In Starling's recent book on "The Fluids of the Body," we have an exposition by a master-hand of the physico-chemical factors which appear to govern the intake, the output, the distribution, and the exchanges of the body liquids. Chemical changes are at the root of all life, and if we seek for a criterion of animate substance we find that metabolism is the distinction between living and lifeless substance.

The possession of the highly complex protein molecule is a definite mark of distinction of the living organism as contrasted with all inorganic bodies (Verworn, *Allgem. Physiologie*, 1909).

Chemical energy is the source of all other forms of energy in the organisation. By its transformations are derived mechanical energy, light, heat, and electricity.

In chemistry, as pointed out by H. E. Armstrong, everything tends to show that function and structure are most closely connected—odour, taste, colour, physiological effect, are specific rather than general properties, each conditioned in its special variety by some special structure (Presidential Address to Section B. Chemistry, at the British Association meeting in Winnipeg, 1909).

The influences of changes of temperature upon the phenomena of life are obviously of high significance, and they have a practical interest for physicians in connection with the pathology of pyrexial affections.

We have learned that the range of temperature compatible with preservation of life is far greater than was formerly thought. The very surprising fact has been established that the living substance of the cells of animals so high in the scale as fishes and frogs can be frozen into ice without losing its capacity for restoration to vital activity.

As for bacteria, Macfadyen has shown that a temperature of  $-252^{\circ}\text{C.}$ —i.e., only  $21^{\circ}$  above absolute zero—failed to destroy the life of certain bacteria even after ten hours' duration of the experiment. Conversely, he has also shown that there are "thermophilous" bacteria, whose optimum lies between  $50^{\circ}$  to  $65^{\circ}\text{C.}$ ; and some cultures will grow at a temperature of  $72^{\circ}\text{C.}$  ( $161.6^{\circ}\text{F.}$ ).

The equilibrium point of a metabolic process can be shifted by alterations of temperature. Take, for example, the potato.

The conversion of starch into sugar is an exothermic reaction—i.e., is attended with extrication of heat. Therefore, in accordance with v'ant Hoff's principle of mobile equilibrium, a rise in temperature will favour the reverse, or endo-thermic process—i.e., the regeneration of starch. Below  $5^{\circ}\text{C.}$  sugar is formed in a potato from starch; if the temperature rises starch will be re-formed from sugar. Similarly, evergreen leaves are, in winter, often free from starch, but contain grape sugar. If brought into a warm room, the sugar vanishes and starch takes its place (Höber, *Physikal. Chem. der Zelle und der Gewebe*, 1902).

So we see that cell physiology is the very root and basis of all physiology, just as atoms are the foundation stones of chemistry.

Calorimetry, coupled with metabolic investigations, leads to the deduction that the energy expended by the body can be quantitatively accounted for by the stores of potential energy contained in the food.

Where, then, is there room for that mysterious *vital force*, or *vital energy*, or *biotic energy* (B. Moore), which, like Melchizedek, has neither father nor mother, and which has so long dominated and enfeebled physiological thought. How do we gain by using a hazy conception expressed in an indefinable word?

The doctrine of the "vital force" is really only a mythological way of expressing the amazement which the unique character of organic phenomena excited (Höfding, "Outlines of Psychology," 1908).

When we say that physiology is and never can be taught else than the physics and chemistry of the living organism, this is not to assert that the forms of energy in living matter are identical with the forms of energy exhibited in non-living structures. And, undoubtedly, there are important phenomena, especially in connection with the nervous system, which lie outside the sphere of experimental inquiry, and belong to pure psychology.

The mystery of life is, probably, an insoluble problem in its ultimate reduction, and, for my own part, I am quite willing to accept Du Bois Raymond's celebrated dictum—*Ignoramus et ignorabimus*.

The fluid nature of living substance is its most important physical property. Hence, the deep significance of the study of colloids, of osmotic phenomena, ionic dissociation, and the varying and complex functions of membranes and of surfaces of separation between the cells of the plant or animal.

From a purely physical point of view, living substances may almost be regarded as animated water (H. E. Armstrong). Or, we may say with Loeb, that all life phenomena are ultimately due to motions or changes occurring in colloidal substances, for Nature works with simple tools.

Another illustration of physico-chemical processes is afforded by catalytic, or ferment, phenomena, which play a dominant part in our physiology, and it is no exaggeration to say that the wheels of life are lubricated by the oil of catalysis. In Dr. Bayliss's recent monograph on "The Nature of Enzyme Action," we have an excellent and lucid exposition of the fundamental problems connected with enzyme action.

In the highest sphere of inquiry—viz., that of mental processes—medical men are not much attracted by the barren speculations of scholastic psychology. Long

ago that monumental genius, Johannes Müller, tersely expressed this feeling in the phrase—*Psychologus nemo nisi physiologus*.

The strange and weird phenomena of mental disease, of hypnotism, suggestion, heredity, instinct, and so forth, will, I am convinced, never be elucidated except by the labours of physiological psychologists, who do not shut themselves up in their studies to dream dreams, but avail themselves, as opportunity offers, of the aids which comparative anatomy and physiology, coupled with experimental science, alone can afford. In this connection I may refer to the excellent textbook of "Experimental Psychology," by Mr. Charles S. Myers (1909).

Human happiness and well-being have been and will be further advanced by physiologists, and for the furtherance of this laudable end it has been proved up to the hilt that it is absolutely necessary to utilise experiments on animals, humanely conducted—a method too often stigmatised by the injurious and inapt term, vivisection.

Sir Samuel Wilks tells a story of an old lady he heard declaiming against the horrors of vivisection. She went on to say that there was no cruelty or dreadful thing that scientific men would not do to find out how things acted. There was nothing that God had created but what they would destroy to look at its inside; but, "thank God," she ended, "they can't touch the beautiful aurora borealis!" (*Brit. Med. Journ.*, July 31st, 1909).

Already a beginning has been made to create a mechanics of the brain and higher nerve centres, and its future is rich in promise.

For example, let us take the law of mass action, which postulates that the course of a chemical reaction depends not only upon the mode of the chemical affinities, but also on the relative quantities of the interacting bodies. Suppose we stimulate a muscle so that its metabolism is continuously increased—i.e., the dissimilation stage of its metabolism is excited—then, automatically occurs a new formation of living substance—i.e., a secondary excitation of the assimilation phase of its metabolism is produced. Thus the deficit is equilibrated, the metabolic equilibrium is restored, the bionous once more = 1. The converse will, of course, happen if the assimilation process is augmented by an increased supply of nutriment.

Thanks to this principle we are able to repair the inroads of fatigue, to overcome disease, and to prolong life (Verworn, *loc. cit.*, p. 595).

Once more, the principle of interference of stimuli is one of far-reaching importance in nerve-physiology and nerve therapeutics, and the phenomena of inhibition can, perhaps, be best interpreted in terms of interference. A familiar example of inhibitory influence is afforded by the facts of snake-charmers, as practised in Egypt and the East from the time of Moses and Aaron until now.

Again, what a vast and fruitful field of inquiry and of practical therapeutics is opened up by investigations upon the effects of auto-intoxications, intestinal and otherwise, upon mental functions.

Have we not gained light and won therapeutic triumphs by a study of the effects on the nervous system of alterations in the internal secretory glands, of the thyroid and para-thyroid, of the adrenals, and of the sexual glands.

But inexorable time presses, and I must not tax your patience with more than one other thought.

By far the most striking illustration of the influence of external conditions upon vital processes is afforded by the different forms of radiant energy, considered as stimuli.

Until recently we were acquainted only with the action of luminous and thermal rays as physiological stimuli, and we have reviewed one or two points in connection with heat rays.

Time forbids to enter upon the fascinating topic of the potent influence of light-rays, considered apart from heat-rays, and it is unnecessary to dwell upon the services rendered by the Finsen light.

Speaking generally, it may be stated that the physiological activity of light-rays is inversely proportional to their wave-length. Hertel has lately made special and suggestive investigations upon this subject. He

arrives at the conclusion that in all probability the general action of light-rays upon living substance depends, in the first instance, upon modifications in the oxygen-exchange.

Fourteen years ago (1895) a new world was disclosed to our ken by the discovery of Röntgen rays, and this was quickly, and logically, followed by the revelation of Becquerel rays, and of the radio-active bodies—viz., uranium, radium, thorium, etc.

Experimental facts have forced us to widen our conception of a "ray." We have now to recognise two kinds of rays—

(1) Streams of particles, of different mass, and with velocities ranging from 15,000 miles per second up to nearly that of the speed of light—i.e.,  $\alpha$  and  $\beta$  rays from radium.

(2) Electro-magnetic vibrations of the ether.

No conclusions of any weight can yet be drawn as to the general physiological action of Röntgen rays, and I pass over the now familiar applications of them to diagnosis and treatment in medicine and surgery.

Among radio-active bodies, especially radium, the  $\alpha$ -rays appear to be the most potent, both chemically and physiologically. From a therapeutical standpoint they can scarcely yet be taken into account, for they are held back by slight obstacles, even by the thinnest mica, glass, or aluminium covering of the tube or vessel which contains the radium salt. The  $\alpha$  particles are completely stopped by a sheet of note-paper, whilst the  $\gamma$  rays from radium can be easily detected after traversing 20 centimetres of lead (Rutherford).

It is, perhaps, possible that we may learn to harness  $\alpha$ -rays to our service by employing either polonium, which yields only  $\alpha$ -rays, or we may perhaps utilise the positive, so-called, "canal rays" of a Röntgen tube.

A position of unquestionable utility has been gained by the employment of the more penetrating  $\beta$  and  $\gamma$  rays, which hang together, and the prospects of radio-therapy are undoubtedly bright. The relative penetrative powers of the  $\alpha$ ,  $\beta$ , and  $\gamma$  rays may be approximately represented by 1 : 100 : 10,000.

It is probably true that radium can effect a cure in certain cases where X-rays fail, but it is premature to generalise.

Everyone here has, doubtless, read some of the already huge literature of the subject, and will recall Sir F. Treves' lecture on "Radium" (*Brit. Med. Journ.*, Feb. 6th, 1909), and the excellent address lately delivered by Dr. Wickham, of Paris, before the British Medical Association in Belfast.

Wickham's pioneer researches were carried out in the Radium Institute in Paris, of which he is director. Thanks to the enlightened foresight of the King, and the generous aid of Lord Iveagh and Sir E. Cassel, we shall shortly have a Radium Institute at home, which will, we feel assured, make weighty contributions to the new science, and add invaluable weapons to our therapeutical arsenal.

## OPERATING THEATRES.

### GUY'S HOSPITAL.

CHRONIC APPENDICITIS WITH ABSCESS OPENING INTO THE CÆCUM.—MR. ROWLANDS operated on a man, æt. 60, who gave a history of a sudden attack of pain in the right iliac fossa eighteen months ago, followed by a high temperature, but no swelling, and lasting for three or four days. He was in bed a fortnight. The bowels were constipated, but were relieved by enemata. He had never been quite well since, having twinges of pain in the abdomen, somewhat worse in the right iliac fossa, but he went on with his work. About a year later, a somewhat similar but less severe attack developed, and three weeks ago he had a third attack. The temperature was raised for four days, but no swelling was felt. This attack, associated with constipation, was followed by diarrhoea and a great deal of colicky pain. Mucus was said to have been passed per rectum on several occasions, but no blood. The patient wasted about one stone in the last six months. On admission, there was nothing abnormal per rectum; the pulse and temperature were normal,

and there was no leucocytosis. A vague swelling was felt rather far in the lower right quarter of the abdomen above the right side of the pelvic brim. This swelling varied in size and shape from time to time, and various alternatives were suggested in the diagnosis:—(1) The history suggested appendicitis with suppuration, which had never entirely cleared up. (2) Considering the man's age, and the fact that he had never been well for eighteen months, and had wasted considerably, a carcinomatous growth about the cæcum seemed possible; the amount of colicky pains, with the visible peristalsis, seemed to support this; moreover, it was not uncommon for attacks of peristalsis to complicate a growth of the cæcum. (3) The variability of size and shape of the swelling, and the colicky pains, suggested chronic intussusception, but the absence of blood was dead against this.

In any case, it was decided to explore. This was done, and an appendicular abscess was discovered the size of a walnut, lying postero-internally to the lower end of the cæcum behind the lower end of the ileum at the root of the appendix, the terminal two-thirds of the appendix lying free in the peritoneal cavity below and internal to the abscess. After the peritoneal cavity had been packed well away, the abscess was opened. It contained muco-pus; its walls were very thick. The appendix was removed, and the stump crushed and inverted in the usual way. It was then discovered that there was an opening from the abscess into the back and inner side of the cæcum near the ileum; this was inverted by means of a purse-string suture. The abscess cavity was thoroughly cleaned and as much of the wall removed as possible. The abdomen was closed except for a small drain leading down as far as the parietal peritoneum only. This was removed in two days, and the patient is doing perfectly well.

## TRANSACTIONS OF SOCIETIES.

### ROYAL SOCIETY OF MEDICINE.

#### OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

MEETING HELD THURSDAY, NOVEMBER 11TH, 1909.

The President, Dr. MACNAUGHTON-JONES, in the Chair.

Dr. A. E. GILES showed a specimen of ovarian adeno-carcinoma weighing 18 lbs., removed from a widow, æt. 60. Also, a case of kraurosis of the vulva of an advanced type, in which a small nodule of carcinomatous growth was just beginning.

Dr. T. G. STEVENS showed a specimen of adenomyoma of the vaginal wall, consisting of two tumours, one situated on the anterior, and the other on the posterior vaginal wall. Both contained cystic spaces lined by columnar epithelium, and he thought from their position and structure that they must be derived from displaced Wolffian tubules.

Also a specimen of fibromyoma and pregnancy with extensive thrombosis of all the veins of the capsule and necrobiosis of many areas of the tumour.

Dr. H. J. PATERSON read a short communication on a CASE OF RUPTURE OF THE UTERUS TREATED BY SUTURE OF THE RENT PER VAGINAM AND DRAINAGE.

The patient, a iii.-para, after premature rupture of the membranes was found to have a prolapsed pulseless cord. Delivery was effected by traction on the foot without difficulty, but on introducing the hand into the vagina after delivery it passed into the abdominal cavity. On admission to the Temperance Hospital, the patient was profoundly collapsed. The vagina was full of blood clot, and a coil of intestine was felt protruding through a large rent in the vaginal vault, through which the fist could be easily passed into the peritoneal cavity. The left parametrium was involved in the tear, and there was free bleeding from two large vessels. These were secured by ligature. Further examination showed that the cervix and lower uterine segment were torn through for four inches, but as the uterus appeared firmly retracted, no attempt was made to define accurately the upper

limit of the tear. The torn edges of the cervix and lower part of the uterus were approximated by three catgut sutures. A large rubber drainage tube was passed into Douglas' pouch and the torn edges of the peritoneum and the vaginal wall were drawn together round it by a purse-string suture. The patient was much collapsed at the end of the operation, but continuous saline proctolysis was maintained for 60 hours, and she ultimately made a good recovery. Dr. Paterson said, as far as he was concerned, the method of vaginal suture and drainage had not been adopted in any of the recorded cases of rupture of the uterus. He thought that some writers laid too much stress on the difficulty of controlling hæmorrhage and Nature's ability to deal with internal hæmorrhage. Suture when possible was to be preferred to hysterectomy, and the cases recorded seemed to show that some of them had recovered in spite of hysterectomy, rather than on account of it.

Drs. COMYNS BERKELEY and VICTOR BONNEY read a paper on

#### LEUKOPLAKIC VULVITIS AND ITS RELATION TO KRAURO-SIS VULVÆ AND CARCINOMA VULVÆ.

The authors pointed out that leukoplakia and kraurosis were two distinct diseases, which could be identified quite easily, both from clinical observation and a pathological examination of the tissues affected. The authors based their paper on the series of 24 cases which they had operated upon and 75 which had occurred in the practice of their colleagues at the Middlesex Hospital and Chelsea Hospital for Women. The authors pointed out that leukoplakia can be differentiated clinically from kraurosis:—

1. By its appearance, which is quite different from that of kraurosis.

2. By its distribution, in that it never affects the vestibule, orifice of the urethra, or vagina, whereas in kraurosis these areas are always affected; and whilst in the latter disease the outer surface of the labia majora and the skin of the thighs and the perineum in their neighbourhood are never affected, in the former disease it is often involved.

3. By the symptoms, for whereas the striking and often the only symptom of leukoplakia is pruritus, this symptom is absent in kraurosis, whilst dysuria and dyspareunia is most marked.

4. By its relation to carcinoma. Leukoplakia is often followed by carcinoma of the vulva, and in every case of this disease which the authors had seen leukoplakia had been present, whilst kraurosis had no relation to carcinoma.

5. By its histological findings. It will be seen that in leukoplakia vulvitis there occurs a diffuse thickening of the epithelial elements with a marked tendency to downgrowth, as exhibited by long inter-papillar processes. The underlying connective tissue is at first the seat of a lymphocytic aggregation, which leads on to a diffuse fibrosis with a total disappearance of yellow elastic fibres in the zone immediately underlying the epithelium. In kraurosis the epithelium is abnormally thin, especially over the red patches seen in that disease. Polymorpho-nuclear leucocytes and massive aggregations of plasma cells are seen, whilst lymphocytes are comparatively sparsely represented. The connective tissue becomes the seat of an atrophic shrinkage, but except at the points of massive plasma cell proliferation, no disappearance of the yellow elastic tissue occurs.

The authors lastly discussed the relationship of leukoplakia to carcinoma, including multiple carcinoma of the vulva, recurrences of the growth, and glandular metastases.

With regard to treatment the authors were strongly of the opinion that all the cases of leukoplakia vulvitis should be treated by excision, because this disease in their experience had been so commonly followed by carcinoma.

The paper was illustrated by a series of micro-photographs demonstrated by the epidiascope.

Dr. A. E. GILES said that there was no evidence in any case of kraurosis which had come under his notice of a history of either syphilis or tubercle, but he regarded the condition as an atrophic one incidental to

the general atrophy affecting the pelvic organs at the menopause.

Dr. AMAND ROUTH agreed that the authors had brought forward very strong arguments in favour of their contention that leukoplakia and kraurosis vulvæ were essentially distinct conditions, capable of easy clinical differentiation. If their contention were correct all modern text-books were wrong, for without exception they described the two conditions under one name—kraurosis vulvæ.

According to the authors, in leukoplakia, pruritus was the main, often the only, symptom, neither the vestibule nor the urethral orifice were ever attacked, but the disease tended to spread over the inner thighs, perinæum and anus, and there was no tendency to contraction of the vaginal orifice. Epithelioma of the vulva very often followed this condition. In kraurosis vulvæ, on the other hand, there was no pruritus, and dyspareunia was the main symptom. The vestibule and urethral orifice were always attacked, the thighs, perinæum and anal region never. The vaginal orifice always became contracted, and carcinoma never developed on the vulva in kraurosis.

He described a case, however, to prove that if leukoplakia and kraurosis were not two stages of the same disease, they sometimes co-existed.

As regards treatment, he had found that the continued application of equal parts of unguentum hydrargyri and unguentum zinci or unguentum plumbi acetatis almost always relieved the pruritus and made the tissues softer and pinker, but the condition was apt to recur. He had not seen any case with a definite history of syphilis.

Dr. W. EDEN said that there was nothing inherently improbable in the idea that leukoplakia was a condition antecedent to epithelioma, for this sequence had been recognised for long in the tongue. He could hardly follow the authors in their recommendation to excise all patches of leukoplakia, since this condition was not at all uncommon, while the malignant transformation described in the paper was comparatively rare.

The President, Dr. H. MACNAUGHTON-JONES, said that the last edition of his text-book was open to the criticism of Dr. Routh, for although the views of many authorities were epitomised, there was no mention of leukoplakia. The two conditions were dealt with under the one term, kraurosis. His experience led him to regard discharge—both uterine and vaginal, and senility, as important factors in the ætiology. No patient he had treated had he known to suffer from carcinoma subsequently. He believed in free excision of the "wash leather" areas, though not to the exclusion of other therapeutic measures such as the application of pure carbolic acid and the use of a 5 per cent. solution of nitrate of silver. He also recommended adrenalin, the use of lanolated ichthyol ointment, and yellow oxide of mercury, with emollient baths, followed by the application of the nitrate of silver. He quoted two cases cured by excision and transplantation of sound skin, combined with the use of the remedies mentioned. He believed that while nothing save excision would suffice in certain cases, yet in others cure could be effected without resource to this severe measure.

Dr. COMYNS BERKELEY, in reply, said that the discussion of his paper had mainly had reference to two points—namely, the ease or otherwise of the diagnosis of these two conditions and the question of the treatment of leukoplakic vulvitis by excision. In reality the two diseases were easy to diagnose, and it was their marked difference which had drawn his and Dr. Victor Bonney's attention to this subject. With regard to treatment, they were convinced that the proper treatment was to excise the diseased areas. He had had the unusual experience of operating upon 18 cases of carcinoma of the vulva all associated with leukoplakia, and at least three of these had been subjected to prolonged treatment for the leukoplakia. He saw no reason why leukoplakia and kraurosis should not occur in the same patient.

MR. GEORGE COATS has been appointed assistant surgeon to the Royal London Ophthalmic Hospital (Moorfields Eye Hospital).

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

### SECTION OF MEDICINE.

MEETING HELD FRIDAY, OCTOBER 29TH, 1909.

The President, WALTER G. SMITH, M.D., in the Chair.

#### ON SOME RELATIONS OF PHYSIC TO PHYSICS, AND THEIR BEARING UPON THERAPEUTICS.

THE PRESIDENT, after some introductory remarks, referred to the decay of homœopathy, and to the rise of "Christian Science," that audacious fraud and moral influenza, the Christianity of which is as *bizarre* as its science is contemptible. Attention was then drawn to the parallel courses of modern physiology and modern chemistry in returning to the closer study of their respective units—viz., the cell and the atom. The general physico-chemical conditions of the human body were briefly discussed, and in regard to the problem of the mystery of life, the President accepted Du Bois Reymond's dictum—*Ignoramus et ignorabimus*. In regard to the highest sphere of inquiry—viz., that of mental processes—it was pointed out that Johannes Müller hit the mark when he said—*Psychologus nemo nisi physiologus*.

In conclusion, the subject of radio-therapeutics was briefly touched upon, and gratification expressed at the foundation of a British Radium Institute.

This paper will be found in *extenso* on page 551.

### SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, NOVEMBER 5TH, 1909.

The President, H. JELLETT, M.D., in the Chair.

#### EXHIBITS.

DR. E. HASTINGS TWEEDY exhibited a specimen of multiple myoma of the uterus. In such cases one would, if possible, perform a myomectomy. But in the case before them it would have been very difficult, as the uterus was absolutely riddled with tumours. It appeared as a smooth myomatous uterus, but on splitting it they could hardly see any muscular structure, and each of the two or three hundred myomas was absolutely distinct, some degenerating, some not. The patient had a temperature, and microscopic specimens had the appearance of malignancy, but Dr. Rowlette told him he could find no malignant disease.

Dr. TWEEDY exhibited a specimen of an ordinary Wertheim's operation in a girl about 24 years of age. There was very considerable ulcerative cancer spreading into the broad ligament. The operation went well until he began to remove the cervical part of the uterus. The cancer then broke away, and he got the end of the vagina. He was able to shut off the intestines, and the woman did not become infected. What was particularly interesting was that he traced up the ureter, and found that while the cancer spread above and below the ureter, it was not diseased. The ureter was so intimately associated with the cervix that in dealing with it one had to hug the cervix to avoid the ureter. He pushed down the bladder far into the vagina, and got his finger between the vagina and bladder. He worked the bladder laterally, and was able to dig the ureter completely out of the cancer, and took away the microscopic evidence of the disease. That was three weeks ago. The patient had gone on very well until a week ago, when her temperature ran up, and a foetid discharge arose. Though she could now hold a certain amount of urine in the bladder, still a quantity passed away, and he had no doubt he was now dealing with a ureteral fistula. In the majority of cases such fistulæ healed spontaneously, but from the accounts which he had read on the subject he found that the ureter practically never became patent again. The urinary discharge would dry up. The ureter cicatrised, and the kidney ceased to secrete. They would only get a hydronephrosis so long as there was some fluid passing through the ureter. If they did not allow a drop to escape through the ureter, the kidney would not secrete urine, and his hope was that

the cicatricial matter would absolutely occlude the ureter, and the kidney would become inert.

Sir WILLIAM SMYLY said ureteral fistula was a risk that anyone was liable to who undertook Wertheim's operation. Recently, when assisting in a case where the ureter had been cut accidentally and where implantation into the bladder was impossible, he had persuaded the operator to ligature it with silk and fix it in the abdominal wound. In that case it was found necessary afterwards to extirpate the kidney.

The PRESIDENT of the Academy said he had once transplanted the ureter into the bladder, and, as far as he knew, no leakage occurred, and no obvious kidney tumour developed. He would be interested to see the result in Dr. Tweedy's case, as it was difficult to understand why hydronephrosis should not occur when the ureter was completely blocked when it occurred where the obstruction was only partial.

The SECRETARY recalled a case of Sir Arthur Macan's in which the urine continued to be secreted as freely as ever from the kidney belonging to the detached ureter, and showed no sign of cicatrization of the cut end of the ureter, or blocking off of the kidney.

The PRESIDENT said one could understand that there was a kind of race between the function of the kidney and the destruction of the substance by back pressure, and would be inclined to think that hydronephrosis would result before the destruction of the kidney substance.

Dr. TWEEDY, in replying, said that he had in his remarks exactly summed up the conclusions of the experiments that he had read, the last being from the Johns Hopkins Hospital within the last six months. The ureter was simply cicatrised over, there was no patency, and the kidney ceased to secrete. Sir William Smyly's case was not on all fours with the condition of spontaneous healing. It was almost impossible to get the ureter to unite permanently by tying.

Dr. PUREFOY exhibited a specimen of pyosalpinx, which had reached a very considerable size in a short time, and had arisen under circumstances which made its origin difficult to account for. The patient had been married several years, and was childless. She had lived abroad, and had had malarial fever and other illnesses incident to residence in a tropical climate. She came under his care for a trifling catarrh of the uterus, and became, as he believed, cured. She went to the country for a few weeks, where she was attacked with what she thought to be malarial fever, with severe abdominal pains and tenderness. On her return to town it was quite easy on palpation to find a tumour having its origin from some of the pelvic organs. He waited for six weeks before operating. On opening the abdomen a rounded tumour came into view completely concealing the uterus, to which it was extensively adherent. In separating it, to his great distress, the sac ruptured, and a quantity of pus escaped. He was, however, happy to add that the patient had an uninterrupted recovery. There was no ground for thinking the condition to be due to any gonorrhoeal affection. There was no evidence of tubercular disease, still he took it that it originated in tubercular salpingitis. She had no signs of tuberculosis, but her family history was unfavourable.

Dr. TWEEDY said it seemed to him worthless to leave a uterus that could be of no use when the tubes were gone. When a tube burst, and pus flowed into the pelvis, it was largely a matter of chance if the patient would recover. If the pus was septic, he knew of no way to avoid the giving of sepsis. If there was any doubt as to the nature of the pus, it would, he thought, be safer to cut away the uterus and the tube at the other side: this would have provided a large hole for free drainage. That hole and the vagina should be packed with a large quantity of iodoform gauze, and the gauze spread out right over the pelvis where the pus had flowed, and where the intestines would come the moment the patient was moved out of position.

Sir W. SMYLY said he had taken out one tube, and the woman had become pregnant afterwards. He did not think it good practice in every case to remove both tubes and uterus, but where there was soiling of the

pelvis, and where both tubes had to be removed, he considered it good practice to remove the uterus also.

Dr. HORNE said he had recently adopted the practice recommended by Dr. Tweedy in a similar case; the patient did very well up to the fifth day, when she complained of pain in the region of the heart, and rapidly sank in a few hours. He wished to ask Dr. Purefoy what treatment he adopted when the pus escaped into the abdominal cavity?

The PRESIDENT thought it difficult to say positively that the case was tuberculous, and he suggested that it originated as one of extra-uterine pregnancy, and that a hæmatoma formed in it and suppurated. He was afraid he was in a minority in thinking it good practice to leave the uterus even if both tubes were removed. If any portion of the ovaries was left behind, menstruation would continue, which was an important matter from the point of view of the mental comfort of the patient.

Dr. PUREFOY, in reply, said it was possible to lift the tumour out of the abdomen to some extent. He had packed the surrounding area with sponges, and the patient escaped contamination from the fact that the adjacent structures had been protected, and the point of exit was outside the incision, and somewhat out of the scene of operations. His recollection was that there was no palpable disease of the other tube, and the case was so serious that he was glad to avoid any unnecessary removal of other parts, and to conclude the operation so far as was compatible with the safety of the patient.

The PRESIDENT gave an address on  
THE TEACHING OF PRACTICAL MIDWIFERY IN THE PAST  
AND AT THE PRESENT TIME,

which will be found in full on page 540.

The PRESIDENT of the Academy said the questions raised were of extreme importance. As a member of the General Medical Council he had a good deal to say to the whole question, and the chief difficulty experienced by the Council was that of proper hospital teaching. In Dublin they were singularly fortunate in that respect, but some of the provincial towns—and even London—were not so fortunately situated, and the principal opposition to the recommendations had come from the licensing bodies, who did not see their way to get such education for their students. Some persons thought the recommendations should have gone further than they did; but some of them, it could not be doubted, would lead to better education. Those of the Council who were not gynæcologists and obstetricians were very strong on the point that students should be clinical clerks and surgical dressers before taking up practical midwifery, so that they might obtain a reasonable amount of teaching in the practice of antiseptics. The General Medical Council could only make suggestions; but their experience was that while some of the recommendations were kicked against at first, they were usually carried out. It had never been necessary for the Council to exercise its power to report the non-adoption of recommendations to the Privy Council, an action which might lead to the degrees of the particular body not being registered. He believed that the recommendations would in time be carried out and strengthened, but they had to move slowly.

Dr. KIDD said he agreed with the President of the Section that a period of six months was one which allowed the student to obtain the necessary knowledge with greater ease than if it was reduced to three months. He thought an alternative might be made with regard to the period spent as an intern in attending a lying-in hospital. A man living inside the walls of a maternity institution saw everything that was going on, he lived in an obstetric atmosphere. If attending as an extern student two nights in the week, whether he saw a case or not, it was difficult for him to devote his attention to lectures next morning. He thought too little attention was paid to the taking of ample notes of cases either in the house or extern, and it should be the duty of assistant masters or clinical clerks to see that notes were taken and signed by the officer of the institution before credit was allowed for the case. When the question of the

clinical examination had first come under his observation, he had hesitated as to the feasibility of its being made practical or practicable; but experience had shown him that the difficulties which he had conjured up were to a great extent imaginary. A practical test was quite feasible as regards palpation, and the general conditions in the puerperium, and questions could be asked to supplement the history that the student gave. He was disappointed in the notetaking.

Dr. TWEEDY thought it was a hardship on the student to cut down the course of instruction to three months. But there was one safeguard in the rules that had lately come into force, which had put the new rule ahead of any of the older forms—the rule that a student had to attend thirty-two times within three months. That rule made it impossible for a maternity hospital to give a three months' course on a one month's residence.

Dr. GIBSON thought the period, instead of being reduced, should be raised to twelve months. But if a man lived in a hospital for one or two months, he would learn far more than from attending twice a week for half a year, and should be spared further attendance.

The SECRETARY agreed with Dr. Gibson. Even in six months, of two nights a week, he did not think one would see a quarter of the number of cases which one would see if resident day and night.

The PRESIDENT of the Academy rose to accentuate what Professor Kidd had said about notetaking. The same thing applied to all other branches of the profession, and the result was that, while their students could hold their own as far as practical subjects were concerned, in competition for the Services, they were very much behind English and Scottish students in the reports of a clinical case, and the commentary on a hypothetical case which formed part of the Army Medical Examination.

The PRESIDENT, in reply, said he recognised the difficulties that existed, and the necessity for advancing with caution and care. They might all agree that the caution and care had been very well marked in the past, and trust that advance in the future would be characterised by more boldness. It seemed to him that for the qualified man there was no question that one month inside was better than three outside, but he doubted whether the average student could assimilate what he saw, as he could if it was spread over a long interval. He was therefore more inclined to agree that the time should be extended to a year. Everyone recognised the practical examination as a great step forward, and the marking should in an entirely new departure, be lenient at first.

#### GLASGOW EASTERN MEDICAL SOCIETY.

MEETING HELD WEDNESDAY, NOVEMBER 3RD, 1909.

The President, Dr. PETER BUCHANAN, in the Chair.

Dr. HENRY RUTHERFURD gave an interesting demonstration on a number of surgical cases in the Royal Infirmary, Glasgow. Dr. Rutherford demonstrated the value of plaster of Paris splints in fractures between the knee and ankle. The ordinary splints to which we had been accustomed in our student days for these fractures were either a posterior splint, Clive's splint, or a half-box splint, but the great drawbacks to these were that there were almost always one of the following conditions developed—pressure, œdema, or stiffness afterwards. Dr. Rutherford in these cases almost invariably uses a "home-made" plaster of Paris splint, and also the same splint for tubercular conditions of the knee. The splint is made to cover only the middle of the foot, and allows free movement at the metatarsal joint. Within 48 hours the splint is cut longitudinally, and at the back, by being of less thickness, it acts as a hinge, and can be replaced at will. The advantage of this method is that you do not interfere with the nutrition of the limb, and give free movement to the metatarsal joint, which is a very valuable addition to the patient when the time comes for him to make any

attempt at voluntary progression, and there is practically no œdema at any time.

Dr. RUTHERFURD also showed a case of intra-cranial pressure in the lateral ventricles. The following symptoms were present: slow pulse, slow respiration, no temperature, slight pain in the head, only occasional sickness, well-marked double optic neuritis, slight facial paralysis, slight weakness of right hand, general stupor, complete absence of irritative symptoms, fœces and urine were passed involuntarily. The decompressive operation was performed, and some 6 to 8 dr. of a yellow spinal fluid were obtained after opening the dura mater. The operation was performed three weeks ago, and the patient is now practically recovered, although a little weakness of the right hand is still present. Specific disease as the cause of this pressure was eliminated by the usual methods.

Dr. RUTHERFURD showed a case of carcinoma recti, where he had operated by simple colotomy, and two cases of goitre, one in a young female, which encircled the neck very much like a collar. The various dangers of operations on these were discussed. Interesting cases of varicose veins were shown, and Dr. Rutherford seems to prefer the operation done by means of Billroth's probe, especially where the veins are superficial, and by this means the skin, particularly in the region of the knee, is left intact, and is a great advance in treatment, especially in those cases where the patient is going to lead an active life in the saddle (public services).

Dr. RUTHERFURD also showed interesting post-mortem specimens of gangrenous hernia, and last, but by no means the least interesting, was a case of extra-uterine gestation, where the patient had had both ovaries removed some months before for cystoma, and afterwards had again become pregnant. From this specimen it appears that a little of one ovary had been left *in situ*, it had also become cystic, and had been the cause of the conception.

## CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

#### FRANCE.

Paris, Nov. 21st, 1909.

#### THREE LITTLE CLINICAL SIGNS.

THREE little clinical signs, produced by pressing rapidly the finger-nail over the skin, or some blunt instrument, in certain nervous affections—red streak, white streak, and local cutis anserina, are frequently of some importance, says Dr. Maurice, as they may materially aid diagnosis in obscure diseases.

The red mark is a streak of the erythematous type, and is more or less intense and durable according to the case.

Its value in confirmed meningitis is well-known, but in a general point of view, as M. Hutinel remarked, it can be found in dyspeptic infants and in children suffering from measles or scarlatina, accompanied with lymphocytosis in the cephalo-rachidian liquid, which could not be traced to hereditary syphilis nor to meningitis, but to a meningeal reaction. In nervous affections erythema in the form of patches is of current observation.

Eppinger and Hess class dermatographism among the signs of irritation of the vagus nerve. In any case, as Hutinel observed, there exists an intimate correlation between erythema and meningeal irritation; consequently the production of a red tracing, either spontaneous (erythematous patches) or provoked (red mark of meningitis), possesses particular clinical value.

The red streak is not, however, an exclusive sign of meningitis, for it indicates also a simple cerebral irritation or an irritation of the pneumogastric nerve, and classes the patients among those who suffer more or less from nervous disturbance.

The white streak was described a few years ago by Sergeant as indicating disease of the supra-renal capsules. According to the author, where, in the course of an infectious malady, with nervous depression,

hypothermia, arterial hypotension, succeeding fever and hypertension, the white streak can be provoked, one is justified in suspecting that the renal capsules are touched, and this fact is of great importance.

The opinion of Sergent has been adopted by Hutinel in the diagnosis of scarlatina, by Martin and Darré in diphtheria, where cardio-vascular asthenia is frequent.

The sign of cutis anserina was first remarked by Vergely in two patients suffering from angiocholitis. It consists in a slight retraction of the skin provoked by a blunt instrument passed rapidly and without violence over the region (hepatic), and lasting about a minute. Vergely concluded that the sign indicated infection, with perhaps suppuration behind the liver.

Although the sign may really exist, it is not special to hepatic affections (as it has been noticed in neuro-pathic patients who presented no trace of hepatic disorder). As a local symptom, it indicates an intense irritation of the sympathetic system, and coincides generally with a tendency to dilatation of the pupil, acceleration of the pulse, paresis of the digestive tract, mental depression and glycosuria. The red mark is accompanied in general with inverse phenomena.

Thus the local sign of cutis anserina is governed by the sympathetic system. In such persons the alimentary régime should be tonic and substantial, and the medical treatment chiefly psychotherapeutic. It is among this class that neurasthenia is prevalent.

The red streak, on the contrary, indicates a certain state of meningitis, and should cause the attendant to prescribe a non-toxic régime, sedatives in the form of warm baths, bromides, belladonna, and, where feasible, change of scene.

Such patients require looking after, as it is among them that melancholia, imaginary persecution, impulsiveness, are to be found.

### GERMANY.

Berlin, Nov. 21st, 1909.

At the Medizinische Gesellschaft, Hr. Blumberg spoke on the

#### SIGNIFICANCE OF CERTAIN PRESSURE AND "RELEASE" PAINS IN REGARD TO PROGNOSIS AND INDICATION FOR OPERATION IN APPENDICITIS AND PERITONITIS.

He spoke of the difficulty met with even by the most experienced in determining early in these affections the prognosis and necessity for operation. He passed the individual symptoms in review, and showed how some were unreliable, how in some cases they had to estimate as a whole, and how in many cases they did not suffice to afford any decided conclusion. Special weight had been laid by all those familiar with the disease on the symptom of pain, and especially pressure pain. From observations made in the course of a number of cases, part of which were operated on and part not, he met with another pain phenomenon, which he first described in 1907 in the *Münch. Med. Wochens.*, No. 24, and which permits the important moment to be recognised in which the inflammation passes to the peritoneum. The existence of such a symptom has been confirmed on many sides, first of all by Ewald, who described it as a "prägnantes" and "markantes" phenomenon.

The inquiry into it is made in this way: The physician presses on the part of the abdomen affected, and whilst the hand is still there, asks the question if it causes pain. After receiving the answer, the palpating hand is suddenly lifted off, when at the moment of lifting a pain is experienced, and the second question is asked whether the pain on pressure or the pain on releasing it is the greater. When the symptom is well marked, the expression of pain may be recognised in the patient's face.

In this way two pains are tested, and a comparison made between the degrees of the two. The test may also be made in another way: You make the pressure test, and then raise the hand slowly; after this you again make the same test, but this time take your hand off suddenly, and then make the inquiry as to whether there was pain from both of the tests, and in which of them it was greater. In making this trial it must be borne in mind that the degree of pressure must be identical in both parts of it. As showing the value of the symptom, the speaker related cases that he had

operated on in which by the use of this symptom it had been possible to determine the severity of the case (for example, gangrene of the vermiform appendix, whilst the other symptoms either failed altogether or were not decisive).

The pain from sudden release of pressure is due to jarring of the peritoneum from the abdominal walls regaining their position rapidly; it is therefore a sign of peritonitis, and consequently also in disease of the female "adnexa," a sign that the peritoneum has become implicated. In recent disease, or in a renewed attack of an old one, the pain on taking off the pressure suddenly is very violent, and distinctly greater than that caused by the pressure itself. As the inflammation subsides both pains are nearly alike; later on the "release" pain becomes less than the pressure pain, at last disappearing, the pressure pain still remaining for a longer or shorter period.

The phenomenon is an early symptom of peritonitis. Kocher ascertained its presence in one case in which an operation was performed within four hours of the commencement of the illness.

The appearance of the sign in a marked manner in appendicitis is a warning signal that specially points to danger when it shows itself suddenly, soon after the commencement of the attack.

Hr. Th. Landau said that he had often had the opportunity of observing the symptom. This method of examination had the advantage that strong and dangerous pressure over the abdomen was avoided. It was not a specific sign, however; it occurred in diseases of women—pyosalpinx, for example—even when the vermiform appendix when brought into view at an operation proved to be quite sound. It was absent also in latent and chronic appendicitis.

Hr. Fulda remarked that two years ago a Roumanian colleague had told him that the symptom was one that was well-known in France, and made frequent use of there. Was Blumberg acquainted with the literature of the subject?

Hr. Blumberg, in reply, said that he had said himself that the symptom was not specific for appendicitis, but that it was of high value in suspicious cases and in the absence of other symptoms, and in the matter of prognosis. In spite of a thorough search into the literature of the subject, which, in connection with the question of appendicitis was beyond all bounds, he had not succeeded in finding any mention of the symptom described before his own publication on the subject.

### AUSTRIA.

Vienna, Nov. 21st, 1909.

#### SPOROTRICHOSIS BOERMANNII.

At the Gesellschaft der Aerzte, Krenn showed a patient suffering from this disease, which was first described in 1903, as prior to that date no case of the kind had been recorded in Austria. The irritant is the sporotrichon Boermannii, which is a finely segmented thread effect in the skin. Two forms appear to be recognised, viz., the syphiloid form, which resembles tubercles, but finally forms pus; the other is called the tubercular form, having a resemblance to lupus with fine granules. The disease is usually not associated with fever, even the most acute cases with all the phenomena of septic pyæmia. Potassium iodide seems to be beneficial where the disease has located itself in the periosteum or bony structures.

In conjunction with this case, Volk showed a few preparations of the sporotrichon, as well as gave a history of a few experiments he has performed with the parasite. The infection was obtained from an original culture from Ravant, and applied to different animals. It is found that dogs, cats, and rats are the most susceptible, some of them having different phenomena from those appearing in the human subject. If the infection be injected intra-peritoneally, it will be found, after 10 or 14 days incubation, the first phenomena will appear in the scrotum as fine poppy seed shining through the albuginea as small glittering tubercles, which have all the appearance of advanced tubercular condition. As the case advances these tubercles are found in the omentum, peritoneum,

lungs, liver, and other organs; finally the animal takes on the cachectic condition and soon dies.

The post-mortems of these animals show that degeneration commences in the parenchymatous tissue of the different organs, while the blood is found to be in a very watery condition.

The preparations were coloured with Gram's solution, which showed the tubercles to be smaller in the centre, but those in the periphery were more virulent. When these tubercles accumulate on the scrotum they form a gummatous ulceration, as described by Krenn.

How this fungus comes to locate itself in the human body is not quite clear, nor can it always be demonstrated, as sections from the human body are found not to contain the sporotrichon, though carefully subjected to Gram's method, while the infection can be transmitted and the morbid phenomena observed.

### SCOTLAND.

**POOR-LAW COMMISSION REPORT.**—The conditions of life in some parts of the Highlands of Scotland are, unfortunately, familiar enough to medical men through the references which are constantly being made to them in connection with medical appointments in that part of the country. Still, it is worth while quoting some paragraphs on the subject from the Majority Report of the Commissioners. In his evidence Dr. Ross, a Medical Officer of Health in the Lews, states that in the parish of Barvas a thousand out of the 1,300 inhabited houses are shockingly defective from a sanitary point of view; men, cattle, and other live stock are housed under one roof without any effective partition wall or separate doors; the excreta, refuse, and slops accumulate in the byre end of the house from spring to spring. Drainage is neglected, and liquid sewage is allowed to escape as best it may. Thinking that the evidence given them might be exaggerated, the Commissioners deputed a committee to report. The Committee thus described the home of a pauper which they visited:—"As we approached the cot of the most distant pauper, we heard the old man singing his psalms, and waited until he had finished, and then entered with one of his married daughters who lived close by. It was the ordinary wigwam style of cot. The floor was rock, and mud, and muck; the fire, before which the old man sat in a little wooden chair, was in the centre of the room; the fowls, which frequented all the houses and made themselves very much at home, were for the most part squatting about amongst the rags on the wooden bed in the inner room." The problem of medical attendance is to secure even a minimum for the inhabitants. The smaller parishes cannot maintain a doctor, and the poverty of the inhabitants makes it impossible for a private practitioner to eke out a bare subsistence. But, besides their poverty, a great deal of callousness exists among the people with regard to calling in a doctor. They are mostly extreme fatalists, and often do not call a doctor on the plea that "the hour has come." Dr. Macdonald, of Stornoway, described the provisions for medical assistance in the island of Lewis thus: "It is a district 72 miles long, with a population of 13,000, scattered over some 40 villages. All the medical assistance available is given by two doctors, 50 miles apart. There is only one driving road, and most of the villages are some distance from the road. The parishes are much cut up by arms of the sea, and villages may be cut off from each other for days, except by walking for days over a trackless moor. There is no provision whatever for isolation of infectious cases. Infectious diseases are endemic, and tuberculosis is becoming general over the island. Seventy per cent. of the deaths are uncertified. The Commissioners add that two remedies were suggested by the Medical Relief Committee in 1904:—(1) A special grant in aid of medical attendance, or (2) the institution of the Irish dispensary system. They are strongly impressed by the need not only for better medical assistance, but by the need for more nurses.

**EDINBURGH SCHOOL BOARD AND THE APPOINTMENT OF MEDICAL INSPECTORS.**—Some time ago the School Board advertised for two Assistant Medical Officers, a man and a woman, at salaries of £250 and £200 respectively. As the latter figure, besides being less than the salary offered to the male Medical Officer, was below the limit fixed by the British Medical Association, no women applied for the post, and the gentleman elected to fill the office subsequently resigned on receiving another appointment. A meeting of registered medical women was held in Edinburgh a week or two ago, at which it was held that the former decision should be adhered to, and that women should not apply for posts at the lower salary. The School Board met the other day, and decided to re-advertise the two posts at salaries of £250, the appointments to be open to men and women. An amendment to advertise for one woman and one man at salaries of £250, and an amendment to adhere to the former arrangement, were put and lost, so that the party of compromise won the day, and if the School Board will only adhere to the spirit as well as the letter of their motion, and appoint a woman as well as a man, they will have succeeded in extricating themselves from an impossible position, and will save their face at the same time.

### BELFAST.

**QUEEN'S UNIVERSITY.**—The Senate of the University met last week, the Chancellor, the Earl of Shaftesbury, K.C.V.O., presiding. The gift of a handsome gold mace from Mr. William Gibson was reported, the mace being on view. The Vice-Chancellor reported that the registration of students was not yet complete, but that already the numbers were far beyond any for years past. A good index of the numbers was to be found in the fact that the class fees already received exceeded by about £1,500 the estimate formed by the University Commission. Sir William Crawford was unanimously elected Hon. Treasurer of the University, and various committees were appointed. It is probable that new buildings will be added at an early date, as the accommodation in various departments is already crowded.

**THE COLERAINE CORONER ON CONSUMPTION.**—A meeting was held last week in Coleraine under the auspices of the Women's National Health Association, at which Dr. H. S. Morrison, Medical Officer of Aghadowey Dispensary District and Coroner for Coleraine, delivered a lecture on "The Influence of Women." After some remarks on the prevailing mortality from tuberculosis in the district, he gave a "straight talk" to the women present, telling them that all the laws on the statute books could never abolish this mortality, but that it was in their power to abolish it by keeping their houses clean and by admitting fresh air and sunshine.

**A SCOTCHMAN ON THE IRISH UNIVERSITIES.**—At a meeting of the Belfast Medical Students' Association held last week, an address was delivered by Dr. G. A. Gibson, of Edinburgh, on "Modern University Ideals." He spoke in terms of warm admiration for the plan on which the Queen's University of Belfast had been formed, and discussed specially the medical curriculum, of which he highly approved. The necessity for the much-talked-of chair of Scholastic Philosophy he recognised, but deplored. The demands of a large portion of the population could not be ignored, even though they introduced the sectarian element. As regards the proposed arrangements for the National University of Ireland and the University College in Dublin, he thought there was reason to fear the future. Continuing, the speaker said: "Instead of trusting to honest work and sound teaching, which were really the only legitimate foundations for a successful educational establishment, the adherents of the new National University had been invoking every influence in order to compel students of medicine to enter the new academic portal and to shun the venerable gates of the Royal College of Surgeons. The terrors of the Church, the threats of Sinn Féin, had been let loose. The fact was notorious. These remarks were not intended to be either ecclesiastical or political in their meaning; all that was contended for was fair play

to everyone. If the new University would manfully and honestly strive to attract students by strenuous exertion in research and in teaching it would speedily attract the respect and esteem of every man of science; but if, on the other hand, it was to persist in a course of conduct like that which it was unfortunately entering upon, it would receive and richly merit the regretful contempt of every right-thinking man."

**DEATH OF DR. ANDREW MCCONNELL.**—One of the senior members of the medical profession in Ulster, and a well-known figure in Belfast, has passed away in the person of Dr. Andrew McConnell. Born in Co. Antrim and educated in Edinburgh, he practised for very many years in Belfast, acting as visiting medical officer to the Union Infirmary till a few years ago. His geniality and kindness of heart, as well as his care and caution in his work, earned him the esteem and affection of all with whom he came in contact. He had ceased to practise for some years past, and found his recreation in the study of history, for, in spite of a very busy professional life, he had always found time to cultivate his literary tastes.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### VIAMI REMEDIES.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—My attention has just been called to a letter published in your issue of November 3rd, dated from Oldham, and signed by a "General Practitioner." Your correspondent boldly accuses the Council of the County Borough of taking money for advertising the Viavi Remedies. It appears from his letters that he caught sight of a notice in a tramcar announcing some free lectures which were to be delivered somewhere in the town by one of the Viavi agents. But why he should venture to assert, as he does, that the Council receives payment for the advertisements displayed in the tramway company's cars, your correspondent does not choose to explain.

For this assumption there is not the slightest foundation in fact. The Council has no pecuniary interest whatever either in the tramways or the advertisements, and has no controlling power over the latter so long as they be not illegal. It is strange that so observant a person should have failed to notice that the tramways are a private, not a municipal, undertaking, seeing that the name of the company is clearly displayed on each of the four sides of every car.

I shall be obliged if you will kindly insert in your next issue this refutation of your anonymous correspondent's erroneous and defamatory statement.

Yours truly,

A. SCARLYN WILSON, D.P.H.,  
Medical Officer of Health.

Health Department, Town Hall, Hastings,  
November 20th, 1909.

[If the construction suggested can fairly be placed on our correspondent's letter of the 3rd inst.—viz., that he "boldly accuses the Council of the County Borough of taking money for advertising the Viavi remedies" in their tramcars, then we unreservedly accept the above statement as exonerating the Hastings Council. It does not seem to us that that is, however, what was meant by our correspondent. (1) It is within the power of any local Council to exercise some amount of control over advertisements displayed within their district. (2) It seems that the municipal authority must necessarily derive income from any trade or business carried on within its area, if only in the one matter of rates. (3) It is hardly conceivable that the towns of Hastings and St. Leonards have made so bad a bargain with the tram companies that they derive no benefit whatever, either by way of rent, or of repair of roads, or of other valuable consideration whereby the Council or the combined Councils benefit from the revenue accruing to the trams. On these grounds we hope that Dr. Wilson will

induce the Hastings Council to inquire more closely into their powers for the regulation of public advertisement, and, where necessary, to take steps to strengthen their by-laws. In any case, we are glad to infer from the tone of Dr. Wilson's letter that he does not differ from our correspondent in his unfavourable view of the Viavi treatment and remedies.—ED. MED. PRESS AND CIRCULAR.]

### A BOARD OF HEALTH AND PHYSIQUE.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—In the *Times* of to-day, November 19th, there appears the long letter, which I enclose, from Mr. Sandow, in which he advocates the establishment of "a board of health and physique, with a Cabinet Minister of the right type at its head." Everyone will agree with the arguments Mr. Sandow uses in support of his ideas, and everyone will sympathise with him in a position which makes it impossible for him even remotely to hint at his own claims to the new office the creation of which he suggests. A few days ago there appeared an article occupying half a page in the *Times* in which the qualifications of Mr. Sandow were set forth. The article was not only adorned by a portrait of Mr. Sandow, and pictures of the interior of his palatial Curative Institute; it also contained a photograph of an audience of medical men listening to an exposition of his system, and—more important than all—a portrait of Mr. Labouchere, proprietor of *Truth*, who has inquired into Mr. Sandow's theories and practice, and vouches for their correctness and success. Mr. Sandow is evidently one of the greatest men living in his department of curative treatment. The *Times* article enumerated twenty-four classes of disease, functional and chronic, including all the vital organs—heart, lungs, liver, kidneys, and nervous system—besides such minor complaints as skin diseases, neurasthenia, and ladies' "figures," all curable by Mr. Sandow's "movement treatment," which can be carried out under his personal supervision or at home, under his prescription, and "occupying but a few minutes of the day." It is to be hoped that when Mr. Sandow's valuable suggestion is taken up by the Government, you, Sir, will not fail to impress upon them his unquestionable claims to the new seat in the Cabinet.

I am, Sir, yours truly,

RUSTICS

November 19th, 1909.

### A MEMBERSHIP DIPLOMA OF THE R.C.S.I.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—Charity begins at home, and I have often wondered why you have never advocated the granting of a membership diploma to the licentiates of the R.C.S.I. The movement for giving the membership to the Scotch licentiates seems to have failed, but perhaps the Council of the Irish College may not be so selfish. In any case the instinct of self-preservation ought to stimulate them to give this small concession of membership to their licentiates, and so put them on a level with the English diplomates.

The College has recently raised the standard of examination for their Fellowship to the level of the R.C.S., England, but the licentiateship requires levelling up, as it is well known to be as searching an examination as is required from the candidates for the English College.

Hoping something may be done in this matter by my old College,

I am, Sir, yours truly,  
AN OLD R.C.S.I. STUDENT.

## OBITUARY.

SIR WILLIAM THOMSON, C.B., M.A., M.D.  
F.R.C.S.I.,

Honorary Surgeon to the King in Ireland.

WITH much regret we record the death of Sir William Thomson, Honorary Surgeon to the King in Ireland, and Senior Surgeon to the Richmond Hospital, Dublin. For several months his life had been ebbing

out, and death relieved him on Saturday, November 13th. He was in his sixty-seventh year.

Though born in Ireland, Thomson was the son of a native of Lanarkshire, but when he was a lad he settled with his mother, after his father's death, in Galway. Here he did journalistic work on his step-father's paper, the *Galway Express*. He later joined the staff of the *Daily Express* in Dublin as a reporter, and became sub-editor. His thoughts had run, however, to the career of medicine, and, while still a journalist, he attended lectures at the old Carmichael School of Medicine, and at Queen's College, Galway. In the latter institution he formed friendships with several men who have since become famous, the most notable being, perhaps, Lord MacDonell. On taking his medical degrees, Thomson settled in Dublin, and before long became Lecturer in Anatomy in the Carmichael School, and a member of the surgical staff of the Richmond Hospital. As time went on, he became one of the best known surgical teachers and surgeons in Dublin, and in 1896 he was elected President of the Royal College of Surgeons. In 1897 he received the honour of knighthood.

In the beginning of 1900, when the generosity of Lord Iveagh equipped an Irish Hospital for service in the Boer War, Sir William was placed in charge. By his foresight and power of organisation, the Hospital was a great success, and Lord Roberts expressed in warm terms his appreciation of its services.

Sir William Thomson took a keen interest in everything of importance to the medical profession. As Commissioner for the *British Medical Journal*, he undertook many years ago an investigation of the conditions of the Irish Poor-law Service, and his report still stands as a document which must be carefully studied by all interested in the problem of Poor-law reform in Ireland.

On the foundation of the Royal Academy of Medicine in Ireland, by the amalgamation of pre-existing societies, Thomson was elected General Secretary, and for several years it was his duty to edit the *Transactions*. For some years he was Direct Representative for Ireland on the General Medical Council. He was a frequent contributor to the medical journals.

His wife, who is a sister of Sir Thornley Stoker, survives him, as do a son and daughter. To them the hearty sympathy of the profession goes out.

Sir William Whitla, President of the British Medical Association, writes: "You place a difficulty before me when you ask me to give you a short notice of my personal appreciation of the late Sir William Thomson, because I feel anything that I can write of him must be in the language of hyperbole, which is liable to sound an exaggeration in the ears of those who were not fortunate in possessing an intimate acquaintance with his inner life and true character."

"In the obituary notices which have already appeared in the medical and lay press, the fact which stands out most prominently is the enormous amount of strenuous public work freely undertaken and persistently carried out by this distinguished Dublin surgeon in the interest of the profession in Ireland and Great Britain. For more than a quarter of a century he maintained a foremost position in the fighting ranks of those struggling against the scandalous hardships inflicted upon the Poor-law Medical Officers of Ireland, whilst during the same period we find him labouring with zeal to weld the heterogeneous elements of the Dublin medical societies into a Royal Academy of Medicine, and with rare courage taking upon his shoulders the heavy responsibility of inaugurating a scheme for the building of the new Richmond Hospital. We next see him at the call of duty leading the officers of Lord Iveagh's Irish Hospital on the march with Lord Roberts to Pretoria, where the best surgical work in the Boer campaign was accomplished."

"Perhaps the most happy years of his strenuous professional life were those in which he represented the practitioners of Ireland on the General Medical Council. Throwing himself into every movement for the reform of medical education, he proved himself a ready, resourceful, and courageous debater. Few

who listened to his fearless advocacy of some cherished scheme for the advancement of his profession, or for the amelioration of the hard lot of the less favoured members of the Dispensary Medical Officers could suspect that the courageous advocate was the possessor of a heart as tender and sensitive as ever beat in a human breast.

"Being honoured and privileged for more than 20 years with his confidence and friendship, I was intimately acquainted with the inward springs of his actions and motives. The attribute which impressed me most, and which was ever evident in our many happy confidential interviews, was Sir William Thomson's chivalrous sense of honour. No temptation of improving his own high professional position, or of gaining the applause of men, was ever for a moment permitted by him to cause the slightest deviation from the high ideal which he had set up for achievement. In positions of delicacy where there was the obvious or almost certain danger of his action being misunderstood or misrepresented, an event from which his sensitive nature recoiled, he never swerved for an instant in his decision to pursue the straight path, always maintaining that the best reward which could come to a man was the proud consciousness 'of having played the game honestly and fearlessly,' as he was accustomed to say during private and confidential conversation. Though a man of the world in the higher sense of this term, with broad culture and a profound knowledge of men and their motives, it was inevitable that with his sensitive nature he must pay the penalty of all noble souls, and wear himself out prematurely in the ceaseless warfare from which he never shrank. It was therefore no great surprise to his intimate friends that within the last two years of his busy life symptoms of general arterial sclerosis set in, accompanied by serious physical signs of heart failure, entailing great suffering, which was borne with heroic fortitude and Christian resignation. Only his life-long friend, the late Sir Thomas Moffett, could have done justice to the many estimable qualities of this truly noble spirit, whose removal has left a dismal blank in the ranks of Irish medicine, but to all who knew him well Sir William Thomson has left an ever inspiring memory, which will continue to bear fruit in the years to come."

#### R. THEODORE STACK, M.D., F.R.C.S.I.

THE news that Richard Theodore Stack has joined the majority will come to many of our readers as a surprise. He has been so long removed from active work (nearly twelve years) that the recollection of his striking figure has become somewhat dim; yet he was a man of such parts as call for more than an ordinary obituary notice, and it is only fitting that his work should be recorded as it deserves.

He was born at Mullaghmore, Omagh, Co. Tyrone, and educated at the Royal School, Raphoe, and Trinity College, Dublin. He took his B.A. and M.B. degrees (first place) in 1873, B.Ch. (first place) in the same year, M.D. in 1874, and M.Ch. in 1875. He had won a classical scholarship in 1868. His distinguished medical career brought him the medical scholarship in 1872, and the travelling prizes, medical in 1873 and surgical in 1874, a record of which any man might be proud, and from which it will be seen that his fine natural ability was enhanced by an industry and application which brought it, one might almost say, to full fruition. In 1873 we find him grinding, along with Yeo and Harvey, in Trinity College, having succeeded to Dr., now Sir Charles Ball, in that triumvirate, keen on the then newer methods of investigation and teaching, and on microscopy, etc.; 1874 saw him in Vienna, and in July of that year he went to Blaenavon, South Wales, as *locum tenens* for his friend Ball during the latter's marriage and honeymoon. While there he was stricken down by rheumatic fever, which, following previous attacks of that disease and scarlatina, left him physically crippled in heart and hearing. It is characteristic of the man that, in his friend's absence, rather than allow him to be worried by the news that his *locum tenens* was laid

up, Stack directed the practice from his sick bed daily by means of assistants, at a time when rest was more essential to his well-being than anything else.

On his recovery he obtained an appointment as physician to the Children's Hospital in Manchester, and while he was performing his duties there he noticed that the children's voices in England seemed softer and less powerful than those he had been accustomed to hear in Ireland. This, which was really due to his advancing deafness, reached its climax when he found himself unable to hear the heart sounds by the stethoscope, and, in a word, his hearing became so bad as to render necessary the resignation of his appointment. None but medical men can fully realise what this misfortune meant; the plain fact is that his deafness had robbed him of his profession, and a career full of brilliant promise was thus at the outset effectually blighted.

This blow, for the moment, staggered him, and he returned to Ireland, to use his own words, "like a hunted hare." He sought the advice of his friends in Dublin, among others, the late Professor Haughton, who suggested he should turn his attention to dentistry. Plucking up courage, he adopted the idea, and, with characteristic energy, he went immediately to study his new profession at the Harvard University, where he took the D.M.D. Harv. in 1877. In this year he returned to Dublin, and practised until 1897, when his health finally gave way. The tragic abandonment of his medical career had excited among those who knew him the keenest sympathy, and his medical brethren, recognising the same ability in his new calling they had seen in the old, gathered to his support with the generosity which has ever characterised the medical profession. Diffident as he was at all times in speaking of himself, those who stood by him at that time may not be aware of how deeply he felt their kindness; but the writer has heard him express himself so frequently and clearly on this, the one gleam of light in his dark days, as to be able to say that he was more grateful than he could express. His practice in Dublin prospered, and he rapidly rose to be one of the leading dentists of that city. In 1897 a stroke of paralysis necessitated his withdrawal from practice, and since that date he lived in retirement. His contributions to the literature of his profession, which had begun when as a medical man he wrote the "Pathology and Diagnosis of Abdominal Tumours in the Male," a work which received the gold medal of the Dublin Pathological Society in 1873, were both numerous and enlightening. Unfortunately, few of them have been preserved. His dental contribution to the Transactions of the Academy of Medicine, Ireland, Vol. I., on "Replantation and Transplantation of Teeth," is still regarded as a classic. Many, however, as were his doings in the world of scientific research, what must be regarded as his life's work lay in another direction. He came back from America fired with the project of founding a School of Dentistry in Dublin. Towards this laudable end he bent every power of which he was master, and with the help of the Corbetts, senior and junior, Robert Moore, John Andrew Baker, William Booth Pearsall, and Arthur Baker, a committee was formed to forward the scheme. As a result of their united labours, a Dental Hospital was opened in York Street in 1879. Its growth in size and in usefulness, both there and after its removal to Lincoln Place, are common property, and, while it is obvious that no man could have performed such a task except with willing and able help from others, it is no overstatement to say that, while his enthusiasm gave it being, he was equally the mainspring in its subsequent progress to usefulness as an educational centre and as a charitable institution. His knowledge of the needs of his profession educationally was early recognised by the Royal College of Surgeons in Ireland, when it appointed him Professor of Dentistry and their adviser generally in matters appertaining to dental education. The British Dental Association also recognised his outstanding eminence by conferring upon him the honour of its Presidency in 1897, when their annual meeting was held in Dublin. That meeting was, in many respects, a record and an epoch-

making event. One of its features initiated by him was the demonstration of the use of X-rays in Dentistry by Mr. W. S. Haughton, an exhibition of scientific method which then little known made a great impression.

In the space at our disposal it is impossible to deal in detail with the work Stack did. From the facts outlined it will be seen that his activity followed a bent the reverse of selfish. While it had, as its aim, the advancement of the status of his profession and the cause of charity, it had the collateral effect of breaking down the isolation which at that time existed between individual dental practitioners and bringing them together and welding them into a cohesive whole.

While the former may be regarded as his work as an educationalist, the latter claims notice as being his doing as a man, and it is a question whether the latter was not a truly greater achievement than the former.

In social life Stack, from his deafness, took to very prominent part, but he was not debarred thereby from occupying a well-known place in the various circles of friends among whom he moved. As a sportsman, he was a good shot (his first attack of rheumatic fever was contracted as a boy from a wetting got after snipe one winter day at Raphoe), a good fisherman, a sailor, and a golfer. He played a fair game of billiards, and from all this we may gather that, while he was largely debarred from conversation, he loved to associate with his fellowmen. His personality attracted most men, and has been described by many as magnetic. His smile, which lit up a face ordinarily pensive almost to sadness, transfused, more than illuminated, his expression, and his unflinching cheerfulness was the best index of his self-dependent mind and character. Among his students he was regarded with something nearly akin to hero-worship, and to all who knew him his faults were seen to be merely on the surface, and were forgotten at the sound of his voice. His life is a record of work done under the gravest physical disabilities, and, if there be any virtue in example, what he was and what he has done must serve as a stimulus to others under like circumstances.

## SPECIAL ARTICLES.

### SUGGESTED AMALGAMATION OF THE ENGLISH DIPLOMA GRANTING CORPORATIONS WITH THE UNIVERSITY OF LONDON.

At the recent annual dinner of the Apothecaries' Society an important suggestion was made by Mr. A. T. Norton, C.B., F.R.C.S., in proposing the toast of the Royal Colleges of the Physicians of London and the Surgeons of England.

My Lord Mayor, Master, and Gentlemen,

I am glad to have the opportunity of proposing the toast of the Colleges of Physicians and Surgeons this evening.

At the present moment, he said, much anxiety and grave responsibility rested on the Examining Bodies of London.

Last year he had foreshadowed the possibility of a combination of the London Examining Bodies, with the object of urging the Government to make such arrangement that the students of London should be able to obtain a University Degree on a parallel with that granted by the Universities of Scotland and Ireland and the Provincial Universities of England.

Since then something had been attempted, but we were in the same position as we were a year ago—indeed 15 or 20 years ago.

If the students of London could not obtain a University Degree they would leave London. They would not come to London. There would be no students of London. This would obviously be a serious matter for medical students, for the medical education and clinical instruction given at the London schools, which could not be equalled in the provinces, would be lost to them. But it would be a catastrophe

for London Examining Bodies and for the London Medical Schools.

He could not conceive it possible that it could be permitted that this Society should be wiped out as an Examining Body, or that this City Company, with its valuable property, attendant privileges, and important investments should be lost to the medical profession. But it certainly would be so if circumstances remained as they now were. Further, he might say that whatever happened to this Company would likewise happen to the two Royal Colleges, and most assuredly they would, though perhaps more gradually than ourselves, cease to be the Examiners of the coming race of general practitioners.

He did not see that the University of London should be called upon to descend from its high pedestal. If it should do so, it would crush the Diploma Granting Bodies unless it incorporated them into itself, and if that took place it would certainly lose that grand reputation which it had ever maintained since its foundation.

That evening there were present representatives of many of the Universities and of the Examining Bodies, and he would ask their permission to make a suggestion, advanced entirely on his own responsibility. He held no brief for the Apothecaries' Company. He could not, of course, enter fully into detail that evening. In a word, he would urge the creation of a new University, to be called the "State University of Medicine," and it should grant the degree only of Doctor of Medicine and Surgery. It should incorporate all Diploma Granting Bodies in the three divisions of the United Kingdom—England, Scotland and Ireland.

There should be but one examination, one set of questions for all, one equalised examination. There should no longer be, and there could not be, a competition of one Examining Body with another by the diminution of the severity of its examinations.

There should be a Council in England, in Scotland, and in Ireland, and a General Council common to all, strengthened by representatives of the State. This Common Council could easily arrange such matters as divisions of fees and curriculum, and other details. He believed that the obstacles to such a University—a one portal to the profession—were few and easy to overcome.

The Universities might at first raise objections, but they could be placated. The great Universities would scarcely be interfered with. They would have to accept the State Degree, and could add what subjects they liked to their own examination. If there should be loss in fees, that loss would be a grant made good from the funds of the State University, taking into consideration the double examination. Those Universities which have taken to examining the general practitioner within the last 25 years or so are they who have bereft us of our inheritance. Yet they should receive justice. The objections of such Universities as that of Edinburgh, which is a great "General Practitioner" Examination University, must receive local consideration and not be allowed to lose either its graduates or its fees.

## REVIEWS OF BOOKS.

### WALSH'S QUACKS AND SECRET REMEDIES. (a)

THIS little book deals practically with a subject to which of late a great deal of attention has been paid both in our own and in other countries, more especially in Australia, Germany, and the United States of America. Not long ago the British Medical Association published a reprint of a series of articles dealing with secret remedies, in which the claims of individual preparations were considered, together with an analysis of their ingredients and estimated cost. The American Medical Association has published a similar book, while the report of the Australasian Royal Commission has furnished an immense work of

reference on the whole subject. Dr. Walsh has gone a step further towards a much-needed control of irregular medical practice and of false remedies, by giving a brief historical sketch of medical legislation since its origin in the days of King Henry VIII., and a careful summary of existing legislation, with suggestions and recommendations for their amendment. He rightly, in our opinion, insists upon the desirability of using existing legislation as far as may be possible instead of attempting to secure the passing of fresh laws. He suggests, among other things, the need of certain reforms in the constitution and policy of the General Medical Council. By the amendment of Section XL. of the Medical Act of 1858, it should be possible to render the control of irregular medical practice a reality instead of a thing of no value, as it is under present circumstances. If the author's contention be correct, namely, that the sale of secret remedies for the professed cure of maladies is simply a branch of unqualified practice, then it would be possible to proceed against many quack remedies with an amended Section XL. A perusal of this book will show that there are many legal ways in which the problem of prosecution of offenders may be brought about. One great want is that of a strong prosecuting body, with ample means to pay the costs of legal action. Dr. Walsh suggests that perhaps the General Medical Council might take up the duty, and that the necessary funds might be raised by rendering the registration of medical men compulsory instead of optional, and by imposing an annual registration fee, as in the case of the lawyers. In view of the recent action of the General Medical Council and of the coming Government inquiry, this book should be of value to all interested in a matter of vital importance, not only to the medical profession but also to the welfare of the community.

## MEDICAL NEWS IN BRIEF.

### The Police and an Injured Prisoner.

RECENTLY, at Battersea, Mr. Troutbeck held an inquest on Charles Highfield, æt. 72, a homeless man, well known at Putney, and believed to have been a soldier. On the evening of October 29th he was found lying on Putney Common, was taken to the police station, and was charged with drunkenness. A constable noticed that his ankle was swollen, but as he was always lame no attention was called to this. Station-Sergeant Bailey stated that Highfield was able to answer questions rationally. The witness did not think it a case for a doctor. He did not see any sign of injury, and when he visited him in his cell the man said he was all right. Other evidence showed that when visited from time to time Highfield said he was all right; at midnight he complained of pain. A doctor was then called in, and he directed his removal to Wandsworth Infirmary. There he died on Monday. Dr. Neal, the Medical Superintendent, ascribed death to heart failure following on a fractured ankle and a broken arm-bone. These injuries, he said, were probably caused on the day the man was found. Sub-Divisional Inspector Jackson said Highfield told him at the infirmary that on October 29th he had been drinking rum all the morning with a man with whom he afterwards went for a ride in a cart. They were thrown out, and he remembered nothing more. The station-sergeant, said the inspector, should have called a doctor. No discretion was given him in cases where illness or injury might be suspected. The matter had been investigated and dealt with by the police authorities. The jury found that death resulted from the injuries, and "they called attention to the neglect in not calling a doctor at the station." The Coroner observed that the police were careful in such matters, and it was rarely indeed that an injured man was not attended to.

Miss ELLISON, late of St. Thomas's Hospital, has been elected Matron of the Royal City of Dublin Hospital.

## NOTICES TO CORRESPONDENTS, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

For ONE INSERTION:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 5s.; 53 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

M. D. (Boston, U.S.A.).—Your important letter has been placed in hands from which in due course an answer will, no doubt, reach you.

CANDIDATE.—M.D., St. Andrews, or M.D., Durham, would in this country rank before M.D., Brux.

VICTIM.—Damages against the quack named could probably be obtained for the deceit and injury described. The commonest of common juries could appreciate the fraud, but you could have a special jury. Consult a solicitor.

COLONIAL.—Why not avail yourself of the post-graduate teaching now to be had in London?

PARTNERSHIP AGREEMENT.—The law will not uphold conditions that are extreme or unconscionable. You could not probably prevent practice at so great a distance from your village; use of the firm's title is another matter.

MEDICAL BURGESS.—The Town Council is the sanitary and educational authority, and administers all legislation in these departments of local government.

DR. DE G. G.—Thanks for letter. We shall be pleased to publish your note as a short original communication. Please add title of paper. The news as to the training of the first Congo native Christian work is interesting from many points of view.

GLASGOW SUBSCRIBER.—The climate of the Riviera, compared with many places now easily accessible, is inferior in many respects when the requirements are uniform high temperature and dryness. Algiers, Egypt, and the West Indies, or even Sicily, might better suit the case of our correspondent.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 24TH.

HUNTERIAN SOCIETY (London Hospital, E.).—4 p.m.: Clinical Afternoon.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m.: Mr. Lockhart Mummery: Clinique (Surgical). 5.15 p.m.: Dr. Leonard Williams: The Diagnosis of Thyroid Inadequacy.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—Clinics: 2.30 p.m.: Medical Out-patient (Dr. T. R. Whipple); Skin (Dr. G. M. Meachen); Eye (Mr. R. P. Brooks). 3 p.m.: X-Rays (Dr. H. Pirie).

THURSDAY, NOVEMBER 25TH.

ROYAL SOCIETY OF MEDICINE (NEUROLOGICAL SECTION) (20 Hanover Square, W.).—8.30 p.m.: Hughlings Jackson Lecture: Sir William Gowers, F.R.S.: Special Sense Discharges in Organic Disease.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, W.).—8.30 p.m.: Dr. A. Morison: The Nature and Treatment of Angina Pectoris.—Mr. J. G. French: Chronic Middle Ear Suppuration—the Sequelae and Treatment.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 p.m.: Dr. Stanley Barnes (Birmingham): Disease of the Cerebral Arteries.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynecological Operations (Dr. A. E. Giles). Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 p.m.: Medical In-patient (Dr. G. P. Chappel).

HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON) (Great Ormond Street, W.C.).—4 p.m.: Lecture (Surgical): Mr. Kellock: The Minor Surgery of Children.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture: Syphilis as it modifies other Eruptions of the Skin: Symptoms, Diagnosis, and Treatment.

FRIDAY, NOVEMBER 26TH.

ROYAL SOCIETY OF MEDICINE (SECTION FOR THE STUDY OF DISEASE IN CHILDREN) (20 Hanover Square, W.).—4.30 p.m.: Cases by Dr. A. E. Garrod, Dr. R. Hutchinson, Mr. K. Bremer (for D. F. E. Batten), Mr. Sydney Stephenson, Mr. O. L. Addison. Specimens will be shown by Dr. R. C. Jewsbury, Dr. H. D. Rolleston and Dr. A. C. D. Firth, Dr. G. Carpenter, Dr. A. C. D. Firth and Dr. E. I. Spriggs. Papers: Mr. K. Bremer:

The Variability and Relative Frequency of the Lesions in Poliomyelitis. Mr. P. Lockhart Mummery: A Case of Strangulation of the Small Intestine by a Band in a child, aged 15 months.

ROYAL SOCIETY OF MEDICINE (EPIDEMIOLOGICAL SECTION) (20, Hanover Square, W.).—8.30 p.m.: Paper: Mr. H. G. Armstrong: Nine Epidemics of Measles at a Public School. Mr. Robert Milne: Scarlet Fever—its Home Treatment.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m.: Dr. Dan Mackenzie: Clinique (Ear, Nose and Throat).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinic: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Operations Clinics: Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 p.m.: Medical In-patient (Dr. R. M. Leslie).

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.).—3.45 p.m.: Lecture: Dr. W. Wingrave: Clinical Pathology.

MONDAY, NOVEMBER 29TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m.: Dr. J. M. H. MacLeod: Clinique (Skin). 5.15 p.m.: Mr. H. A. Ballance (Norwich): Fractures of the Lower End of the Humerus in Children (illustrated).

TUESDAY, NOVEMBER 30TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chancery Street, W.C.).—4 p.m.: Dr. J. W. Carr: Clinique (Medical). 5.15 p.m.: Mr. Harold J. Stiles (Edinburgh): Treatment of Hernia in Infants and Young Children.

## Appointments.

COATS, GEORGE, M.D. (Glasg.), F.R.C.S. Eng., Assistant Surgeon to the Royal London Ophthalmic (Moorfields) Hospital.

DAVIES, IVOR J., M.B., B.S. Lond., Resident Medical Officer at the Farringdon General Dispensary, E.C.

GRIFFITHS, JOHN S., L.R.C.P. Lond., M.R.C.S., County Director of the British Red Cross Society for Bristol.

HAMILTON, ARCHIBALD, M.R.C.S., L.R.C.P., House Surgeon at the Chelsea Hospital for Women.

WARING, H. J., M.S. Lond., F.R.C.S., Surgeon to St. Bartholomew's Hospital.

## Vacancies.

West Riding Asylum, Wakefield.—Assistant Medical Officer. Salary £140 per annum, with apartments, board, washing, and attendance. Applications to the Medical Director at the Asylum.

North Cambridgeshire Hospital, Wisbech.—Resident Medical Officer. Salary £150 per annum, with unfurnished house. Applications to William F. Bray, Secretary.

Cancer Hospital (Free), Fulham Road, London, S.W.—Physiological Chemist to the Cancer Institute. Salary £350 per annum. Application to the Secretary.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—Assistant Casualty Medical Officer. Salary, for six months, £30, and washing allowance £2 10s., with board and residence in the hospital. Applications to the Secretary. (See advt.)

The Hospital for Sick Children, Great Ormond Street, W.C.—Ophthalmic Surgeon. Applications to the Secretary. (See advt.)

The Hospital for Sick Children, Great Ormond Street, London, W.C.—Resident Medical Superintendent. Salary 100 guineas per annum, with board and residence in the Hospital, and £5 washing allowance. (See advt.)

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Surgeon. Applications to the Secretary. Salary for six months, £30, washing allowance £2 10s., with board and residence in the Hospital. (See advt.)

## Births.

SCORESBY-JACKSON.—On Oct. 28, at Abu Rood, Rajputana, India, the wife of Thomas Scoresby-Jackson, M.B., etc., of a daughter.

WARREN.—On Nov. 20, at 15 Lansdowne Crescent, London, W. the wife of Alfred C. Warren, M.D. Cantab., of a daughter.

## Marriages.

CLUDE-HAILEY.—On Nov. 22nd, at St. Outhbert's Church, Philbeach Gardens, London, S.W., William Leslie Brutton Clude to Violet Madeline Hailey, youngest daughter of the late Hammett Hailey, M.D., and Mrs. Hailey, Philbeach Gardens, London, S.W.

## Deaths.

SWEETLOVE.—On Nov. 18th, at Sutton, Surrey, John Wallace Sweetlove, M.R.C.S., L.R.C.P., elder son of the late Robert Sweetlove, of St. Leonards-on-Sea, and of Mrs. Sweetlove, of East Molesey, aged 38 years.

**REQUIRE D** for agreeable position with quite exceptional prospects, a medical man with much experience of Abdominal Hernia and Truss Fitting. Must be intelligent, energetic, and anxious to create for himself by conscientious and assiduous attention to work a first-class situation. Also required expert translator from the German for a treatise on E. PEARL. Write stating full particulars to Box, No. 10, MEDICAL PRESS AND CIRCULAR.

# THE MEDICAL PRESS AND CIRCULAR.

No. 22.

## NOTES AND COMMENTS.

### Arsenical Wall-paper

THE death of a prominent Vienna financier has been ascribed to poisoning from an arsenical wall-paper. The medical attendants, according to the special correspondent of a London newspaper, state death to have been due to calcification of arteries, "accelerated by the poison contained in the green paper of his studio and reception-room." It must be owned that the alleged active agency of the incriminated wall-paper would be more convincing in the absence of a concurrent malady of a serious nature. The evidence, however, appears to have been considered sufficient by the Vienna Public Prosecutor, who, after investigation by the police, holds the firm that supplied the wall-paper a year ago responsible. The whole stock of that particular paper, moreover, has been seized by the police. The final fact with which we British as a nation are concerned is, that the arsenical paper was imported by a Vienna firm from England. If this be the case, there seems little excuse for the legislature that still permits the manufacture and sale of papers containing arsenical pigments. The harmfulness of hanging paper thus prepared has been known to medical science for two or three generations, and it is a standing reproach to our national common-sense that so insidious a danger to health should be permitted to linger amongst our industries. Plenty of vivid green and other arsenical tints can be imitated precisely without the use of that or any other injurious metal. But the facts have still to

### And other Poisonous Metals.

be proved. If arsenic be used by our wall-paper makers, it can only be to an extremely small extent, and before we admit the truth of the Austrian innuendo, the case must be proved up to the hilt. For all that, it must be confessed that it took many years of effort to eliminate the poisonous form of phosphorus from our industries. Lead has been only partially eliminated, for in spite of a vast deal of industrial legislation, many cases of plumbism are reported annually. A large proportion of this mischief arises in connection with lead glaze. Now it has been shown that equally good results can be obtained by the use of a leadless glaze. Some day that fact will penetrate the recesses of the Home Office, and steps will then be taken, it is hoped, to remove this preventable loss of industrial life by the compulsory substitution of leadless for the prevailing lead glazes. The curious compound of conservatism and enlightened progress that characterises the Anglo-Saxon character is never more apparent than in their treatment of a matter of this sort. The British lead the van, and always have led the van, in the legislative protection of industrial life, but having boldly taken the

first great steps, they permit details to drift on for generations without the slightest attempt at remedy. Nevertheless, our sanitarians have much to be thankful for in many directions.

### Sanitation of Malta.

IN our issue for the 10th of last month, under the heading "Sanitation, General and Special," we deprecated mixing up the results of general and special hygienic efforts, dealing more particularly with the reduction of Malta fever among soldiers and sailors by prohibiting the use of goats' milk. Unfortunately, this fallacy has been flaunted in the lay press by a medical man notorious for his opposition to compulsory vaccination, and Mr. Lupton, M.P., asked the Secretary for War, on Thursday last, whether sanitary improvements, in the way of drainage and cleansing of the harbour, had been effected in Malta; if a large portion of the garrison had been removed from the low-lying barracks at St. Elmo to new barracks on the hill; if the cases of fever in the garrison had been reduced to a small proportion of their former number; if he would remove the prohibition on the use of goats' milk by the garrison, the latter having been conclusively proved "not guilty" by a medical writer? Mr. Lupton then wound up with an *ad misericordiam* plea on behalf of the farmers of the island. The Secretary of State for War (Mr. Haldane) is, fortunately for medicine on this occasion, a member of the bar, and he has evidently been able to weigh the evidence for and against the goats' milk. In his reply he presented an overwhelming case against the milk, saying it was "so marked that no responsible Minister who did not wish to be regarded as weak and incompetent would venture to remove the prohibition for the use of goats' milk by the garrison," a remark received by cheers and laughter. It seems to us that Mr. Lupton, like many worthy persons not read in the methods of scientific thought, attaches too great importance to single and uncorroborated utterance.

### Laxity in Medical Certification.

It must be admitted that, to a certain type of professional conscience, a laxity in the signing of certificates, be they paid for or otherwise, is looked upon casually as a quite moral offence. In much the same way, many persons are ready to defraud the revenue by smuggling, whereas they would hold any other ordinary breach of the law as anathema. Yet both the smuggler and the careless attestor of certificates is apt to be caught now and then in the act, whereupon follows the Nemesis of speedy exposure and punishment. At the disciplinary sitting of the General Medical Council, last week, a

London practitioner was convicted, in that while he was a certifying surgeon under the Factory and Workshops Act, 1901, he had employed another registered practitioner to conduct examinations for him, having signed by himself certificates that he had personally examined certain persons on certain dates and that they were fit to perform work on which they were engaged. On these grounds the defendant was charged with having systematically attempted to mislead the factory inspector. The facts being proved, the Council had obviously no choice but to find him guilty of infamous conduct, in a professional sense, and to strike his name off the *Register*. All medical men who are tempted to stretch a point in signing certificates, whether from good nature, laziness or want of care, will do well to think of the unpleasant consequences that may follow at any moment from their unwise action.

#### Unqualified Electrical Treatment.

LAST week an action was successfully brought for damages for personal injuries against the Dowsing Radiant Heat Company. The plaintiff was treated with a high frequency current, and got burnt, apparently, because of some metallic braid on plaintiff's skirt. A qualified medical expert stated as his opinion that high frequency required skilled administration. The jury returned a verdict for the plaintiff to the tune of £60 damages, and the judge observed that there was nothing to complain of with regard to the defendants, the occurrence being more of an accident than anything else. With all due deference to his lordship's views, it is difficult to see in what material respect unqualified electrical treatment differs from any other kind of unqualified medical practice. It seems clear enough that the proper administration of electricity for curative purposes demands special medical training, above and in addition to special technical knowledge of electrical matters. Should a person suffer any injury through the administration of electricity by an unqualified person, it seems that the latter should be liable to heavy damages. Had it not been for the supineness of the Royal College of Physicians of London for the last four hundred years the host of unqualified medical practitioners would never have been permitted to come into existence. As things go, we have the extraordinary spectacle of a judge on the King's Bench who sees "nothing to complain of" in the exercise of medical functions by unlicensed persons.

#### Counter- prescribing.

ON the 22nd ult. the three Direct Representatives of England and Wales, Dr. Langley Browne (West Bromwich), Dr. Latimer (Swansea), and Dr. L. S. McManus (London), met the members of the Metropolitan branch. They gave an interesting account of the work of the Council and of the part they had taken, and hoped to take, in reforms. One of the most encouraging things from the point of view of the general practitioner is the opening of the campaign against unqualified practice. There was little discussion upon the speeches, and, curiously enough, the main subject discussed was that of counter-prescribing. Dr. McManus explained that some years ago the Council had conferred with the Pharmaceutical Society upon this matter, and the position taken by the pharmacists was, "Let medical men drop dispensing and we chemists will stop prescribing." That was apparently regarded as a deadlock on both sides. We venture to differ absolutely from a conclusion that we regard as futile and illogical. Medical men are perfectly

within their right in dispensing, and had the profession been properly protected by the colleges the Pharmaceutical Society would never have come into existence. On the other hand, the chemist who prescribes is committing a gross act of unqualified medical practice, as he will some day find to his cost when the control of unlicensed practice is put on a sound footing. For the pot to call the kettle black when the pot has got nothing to stand on is to put forth a foolish variant indeed of the old fable!

## LEADING ARTICLES.

### THE GENERAL MEDICAL COUNCIL.

THE session of the General Medical Council which began last week is not likely to be marked by any momentous issues. The address of the President, Sir Donald McAlister, was devoted chiefly to the official account of communications with colonies and dependencies regarding the Medical Acts, and of work done by the Pharmacopœia and other committees. The important question of anæsthetics was mentioned, and it was stated that the committee appointed to deal with the proposals for legislation upon this subject had been officially informed that there was no likelihood of anything further being done in the present parliamentary session, but the Chairman of the Departmental Committee had asked that any further Council resolutions dealing with the matter should be submitted to him. As regards legislation on this particular point, it certainly seems desirable that Parliament should be guided by the advice of the most authoritative medical opinions that can be obtained. It would be unwise to attach undue weight, for instance, to the views of anæsthetists, of surgeons, of teachers in medical schools, of dentists, of coroners, of lawyers, or of the intelligent man in the street. Any sound conclusions must be based on a careful and impartial examination of the subject from all points of view. Above all, it should be borne in mind that, owing to the lack of sufficient data, the basis of the science of anæsthetics is faulty, and that meanwhile legislation must be to a corresponding degree tentative. Sir Donald McAlister also alluded to the objections taken in May last, on legal grounds, to certain provisions in the proposed draft charter of the British Medical Association, which had been communicated to the President of the Privy Council, and that it was probable that an amended draft would in due course be substituted by the Association. It is well for the General Medical Council to keep an eye on anything that may tend to decentralise or weaken, however unwittingly, the effect of existing powers, in which apparently trivial charges may be fraught with grave and far-reaching consequences. In the year 1860 for instance, the Royal College of Physicians of London introduced a short Act to amend the Medical Act of 1858, whereby the letters testimonial and the "elects" were abolished. It is open to question whether the abolition of the "elects," in whom the summary powers of the College were vested as regards quacks and quackery, did or did not at the same time destroy the penal powers of that body. The

amending Act was passed shortly after the creation of the General Medical Council, when it was hardly likely to be experienced enough to weigh the consequences of the proposed change. The College of Physicians, however, apparently consider that their penal powers persist in spite of the abolition of the "elects" in 1860, for it is only last year that they insisted on those rights in opposing the draft charter of the British Medical Association. It is to be hoped that the General Medical Council will take some strong and vigorous steps in the direction of clearing away the fog that surrounds the mazes of medical legislation, and will urge upon Government, through the Privy Council, the necessity of the strengthening and consolidation of existing medical law. In no other way can the interests of the community be properly safeguarded. Nor need we despair of the future as regards the Council. Of late there have been many signs that a new and more liberal spirit is pervading the council chamber of that august body. Resolutions are now considered that were formerly dismissed with a scant plea of *non possumus*. The important point of unqualified medical practice has been taken up, and on every side there are indications that the General Medical Council is about to add to its duties the protection of the public against unqualified medical practitioners, in place of their former policy of drastic discipline confined strictly to duly qualified medical men. The note of confidence in the future development of the Council was conspicuous at the recent meeting of the Direct Representatives of England and Wales with the Metropolitan Practitioners. The medical profession owes a debt of gratitude to their direct representatives, past and present, but it must be remembered that the pressure for reform should come from without, and that such pressure should be strong and persistent in order to bring about various changes of vital importance, both in the constitution and in the policy of the General Medical Council.

#### WORKMEN'S COMPENSATION AND REFUSAL TO SUBMIT TO OPERATION.

THE manufacture of case-law in the Workmen's Compensation Act is going on apace, and it is desirable for medical men to keep in touch with the trend of judicial decisions, in order that they may advise their patients wisely. The question of refusal to submit to operation on the part of an applicant for compensation has cropped up from time to time. It appears that, speaking broadly, the refusal must be "reasonable," that is to say, that there must be little doubt as to the probability of success of surgical interference. There are, of course, other less direct reasons that might be maintained as justification for refusal, such as, for instance, a state of general enfeeblement or of cardiac disease that would render the administration of an anæsthetic more than ordinarily hazardous. In a recent case tried before the Court of Appeal a somewhat important variation of the question of refusal as usually presented was adjudicated upon. The main facts may be gathered from the *Times'* law report, of which the following is a brief summary:—A foreman, named Marshall, claimed com-

pensation from the Orient Steam Navigation Company for injuries sustained in the course of his employment. A burn on the fingers of one hand became septic, and four days after the accident was lanced by the ship's surgeon, who next day suggested several free incisions in the hand itself, but this was declined by the patient. Ultimately the applicant went into hospital, where a finger was amputated. The ship's surgeon gave evidence at the subsequent trial at the County Court of Essex that, in his opinion, if the operation had been performed the finger would have completely recovered. The learned County Court Judge came to the conclusion that the applicant would have perfectly well undergone the operation, and that it was unreasonable for him to refuse to submit to it. His Honour, however, held that, as another doctor who saw the applicant later had given evidence that in his opinion the finger was so implicated that the operation could not have saved it, he could not say whether the operation would have saved the finger or not, and as in fact the finger had been lost, there must be an award in favour of the applicant. The decision was appealed against by the employers. The Master of the Rolls, in dismissing the appeal of the employers, remarked on the difficulties presented by this class of cases, as to which he had been sanguine enough to think that the Court had laid down rules for the guidance of the County Court judges. In the case under consideration, the first question was, whether the man was unreasonable in refusing, the next, whether the loss of the finger was due to his unreasonableness. He referred to a previous judgment of his own in *Warneken v. Moreland* (1909, 1 K.B., 184, at p. 188), which ran: "I do not understand how anyone can doubt that, under the present circumstances, the true inference of fact is that the continuance of the incapacity is not due to the original accident, but is due to this workman's unreasonable refusal to take a step which any reasonable man would willingly submit to." It was an issue of fact in Marshall's case for the County Court to say whether the refusal was reasonable or unreasonable; but that was not enough, he must go further, and say whether the continued disability was due to the accident or to the unwillingness to submit to the operation. The burden of proof that something had happened, the result of which was that the loss of the finger had not been due to the accident; but it was impossible to show that operation would have saved the finger. The appeal was accordingly dismissed.

#### CURRENT TOPICS.

##### Anti-Vivisectionists and Cruelty to Animals.

ONE of the unfortunate results of the so-called anti-vivisectionist movement is that the reputable organisations for the prevention of cruelty to animals are being embroiled and brought into disrepute. No one will deny that the National Society for the Prevention of Cruelty to Animals has done much humane and useful work, and it is to be regretted if its activity is impaired in the future. In some districts, however, trouble is being caused by the violence of the anti-vivisectionists, and local

branches are in danger of disruption. In Dublin, for instance, where the branch has already suffered much from dissension, we understand that at a recent meeting held in private, a bye-law was carried making an anti-vivisectionist pledge a condition of election to the committee. As a result, there is likely to be a secession from the ranks of the subscribers to the Society for the Prevention of Cruelty to Animals, as many who give their cordial support to that organisation have sane views as to the freedom required by research. The result of the anti-vivisectionist revolt is that grave injury is done to the movement to safeguard the comfort of animals.

#### Slum Property in Dublin.

LAST week, during certain repairs to a tenement house in Dublin, the house collapsed and two lives were lost. The evidence given at the inquest on the unfortunate victims disclosed the fact that for the past eight years the attention of the Sanitary Department of the Dublin Corporation had been directed to the condition of the house in question. Since 1901 no less than twenty-six notices had been served on the landlord in respect of this one house, the defects being in some cases structural, in others sanitary. For eight years, therefore, the municipal authorities had been aware of the condition of the premises, and in spite of this it collapsed, killing two men. There is no question that it was within the powers of the Corporation compulsorily to close the premises, but though closing notices were served, they do not seem ever to have been enforced. Apart altogether from the startling end of the incident, the fact that it is possible for a landlord to keep his premises in such a condition as to require twenty-six notices in eight years is a curious commentary on the efficacy of Dublin sanitary methods.

#### Damages for Barber's Rash.

THANKS to modern scientific advances, the infectivity of that most troublesome and disfiguring malady known as "barber's rash" has been established. From that knowledge it follows that the condition is preventable, and, as a necessary further conclusion, that the barber who infects a customer by the use of uncleanly instruments in shaving must be held responsible for the consequences. At the Hull County Court, on November 16th, a local watchmaker sued a barber for £50 damages on account of "barber's itch," caused by being shaved by defendant's lady assistant with insanitary instruments. The facts were proved, and it was admitted that defendant had notices about his shop, "Cleanliness is next to Godliness," "Beware of Dirty Shaves," "Fresh water for Every Customer—One Penny." It was shown, however, that fresh water was not always supplied. The defence fell back upon the two-edged argument that elaborate precautions could not be adopted when there were many customers to be attended to at the same time. With regard to that plea, His Honour remarked that all that was wanted was a decent clean shave, and that seemed possible when the defendant was not too busy. He gave judgment in favour of plaintiff to the extent of £25, and costs. Considering the extent to which barber's rash prevails, and the fact that it is absolutely avoidable by the use of

proper precautions in the sterilisation of instruments and other articles used in shaving, it is a matter of wonder that actions for compensation are not of more frequent occurrence.

#### The Housing Bill.

THE Housing Bill, after dragging its slow length along the floor of Parliament during two Sessions, has at length passed both Houses, and now awaits the Royal Assent. The Government adhere to the position they first took up with regard to county medical officers. It will be obligatory upon all County Councils to appoint officers, and they will be irremovable except with the consent of the Local Government Board. This will somewhat improve the status of medical officers, but will not give them an assured and independent position. As we have over and over again insisted, everything must always depend upon the personal qualities of the local bodies. They may be rendered unable to dismiss an officer, but they can still make his position intolerable to him, or, at least, put such pressure upon him as will reduce him in many cases to complete subordination. The recent treatment of the medical officer by the Council of Kingston—the Surrey county town—was, in this connection, sufficiently suggestive. Neither this new step nor any other provision of the Housing Bill can be productive of much good unless local patriotism becomes much more recognisable than it is at present throughout the country. Less than 50 per cent. of burgesses will take the trouble to record their votes for candidates for local bodies, whilst men of capacity, as a rule, will neither come forward to serve nor to take any part in selecting and supporting them when in office. Illustrations of the comparative failure of sanitary legislation all over the country due to these causes are appearing from week to week in these pages.

#### Supported by Voluntary Contributions.

FROM week to week more or less striking evidence is forthcoming of the failure of the system of voluntary contributions to furnish income sufficient for the maintenance of our hospitals. The Great Northern's difficulties are now being set forth in enormous newspaper advertisements, which must be in themselves consuming a considerable income. The hospital's last annual income was £3,000 short, and it owes the bank over £14,000. Upon this Sir G. C. T. Bartley, who has been examining into the sources of the hospital's funds, offers some pertinent criticism. He finds that the hospital receives virtually no local support. The population it serves numbers 500,000; among them together they subscribe only £480, or about a penny a family per year. This seems a very weak argument for outside help, for which the appeals are being made, seeing that the great bulk of the inhabitants are well-to-do, and support the average number of public houses, besides places of amusement of every class. Sir G. Bartley points out that an average subscription of 1d. a week per family would not only supply the £17,000 required for the upkeep of the hospital, but would give in addition some £4,000 a year for extension. If the subscription lists of other London hospitals are examined, it will be found that the same thing prevails pretty generally. The bulk of

the subscriptions to all hospitals comes from wealthy and benevolent people, upon whom personally the institutions have no claim, and comparatively little is provided by the inhabitants of the locality, who all directly or indirectly participate in the benefits of the hospital. So long as money can be obtained from any source, the present system will no doubt be continued; the alternative of municipal hospitals supported by the rates is not likely to be adopted very willingly.

#### The Declining Birth-Rate.

To the numerous correspondents who have from time to time sustained an animated controversy in our columns with regard to the exact significance of the falling birth-rate, a phenomenon which is now making itself more and more aggressively prominent among the people of these islands, the recently-issued work of Mr. W. C. D. Whetman, F.R.S., may be heartily commended. The book, which is entitled, "The Family and the Nation," is quite up to the high level to which previous scientific writings of the author have reached. There can be no doubt about the diminishing quantity of the population, and there can be no doubt about the effects upon the nation's fate in some directions which must result when the decline becomes absolute. The experiment has been made in France, and has already produced a relative national weakness which is becoming a source of greater and greater anxiety to her statesmen. The question was once more discussed in the Chamber last week during a debate on the Budget, when M. Briand, Prime Minister, and M. Barthou, Minister of Public Works, dwelt upon the enormous importance of the subject. The deaths in France during the first six months of this year have exceeded the births by 28,203. The question of quality is, within certain limits, of more importance than the question of quantity; and if it were certain that a falling birth-rate were necessarily accompanied throughout the mass of the people by production of offspring physically and mentally superior, misgivings for the future might, perhaps, be minimised. The author, however, enlarges upon the fact that there is really being carried on a gigantic system of artificial selection which encourages survival of the unfit. Among the classes of the nation that, in virtue of physical and moral qualities, have valid claim to be styled superior, including skilled artisans, the birth-rate has fallen fully 50 per cent. in forty years, whilst no fall has taken place among the lowest classes—casual labourers and wasters. The problems are worked out so far as possible from the standpoint of evolution in the work to which we refer, and the remedial measures suggested lie in the direction of the national organisation of eugenics—a view which is now adopted by a growing band of scientific sociologists.

#### PERSONAL.

THE KING in Council has been pleased to appoint, among others, Miss E. M. N. Williams, M.D., D.P.H., to be a member of the Senate of the University of Durham.

PRINCESS VICTORIA OF SCHLESWIG-HOLSTEIN presided at the annual meeting of the St. George's Hospital Work Society at St. George's Hospital.

PROFESSOR PRIESTLEY SMITH occupied the chair at the fourth of the special course of lectures at Birmingham Institutions, given under the auspices of the Workers' Educational Association, and delivered at the University, on the 24th ult., by Alderman J. H. Lloyd, upon "The Hospitals of Birmingham."

THE Duchess of Northumberland has sent a full-sized billiard table to the men's wing of the Royal Hospital for Incurables.

DR. J. J. PURSER, Anaesthetist to Dr. Steevens' Hospital, Dublin, has been elected Assistant Physician.

DR. MOON will contest the East Marylebone parliamentary division of London at the next election, in the Liberal interest.

DR. E. MARSHALL is one of the recipients of the King's medal in silver to commemorate the Shackleton Antarctic Expedition, 1907-9.

HER EXCELLENCY THE COUNTESS OF ABERDEEN opened a food and cookery exhibition on November 24th in the Rotunda, Dublin.

DR. T. HOBBS CRAMPTON was presented with an illuminated address, on November 24th, by the Irish Medical Schools' and Graduates' Association.

MRS. SIBYL ANNE TAIT, who died on August 27th, was the widow of Mr. Lawson Tait, F.R.C.S. Her estate is valued at a net personalty of £11,089.

DR. E. HASTINGS TWEEDY, F.R.C.P.I., Master of the Rotunda Hospital, has been elected Gynaecologist and Obstetric Physician to Dr. Steevens' Hospital, Dublin.

PROFESSOR A. CRUM BROWN, F.R.S., who is well known to Edinburgh graduates, was recently presented by his old pupils with his portrait, painted by Mr. A. E. Walton, R.S.A.

MISS HARRIMAN has recently purchased the ferry-boat *Eric*, which she has had transformed into a usefully equipped school for the children who are affected with tuberculosis.

THE new botanical laboratories at University College will be opened on Friday, December 17th, by Dr. D. H. Scott, F.R.S. The Vice-Chancellor (Professor M. J. M. Hill) will preside.

EMERITUS PROFESSOR THOMAS PURDIE has offered to the University of St. Andrew's the sum of £2,000 to provide the salary of an assistant in the Purdie Chemical Research Laboratory.

Mrs. GEORGE H. LODGE, L.R.C.P. and S.Ed., L.D.S., R.C.S.S., formerly Mayor, now Deputy Mayor of the borough of Rotherham, has been added to the Commission of the Peace for that borough.

ON the occasion of his jubilee as a medical practitioner, Dr. James Whiteford, Greenock, was recently entertained to dinner by the Faculty, and presented with a cheque for £100 and a silver salver.

SIR FREDERICK TREVES, BART., F.R.C.S., G.C.V.O., has been appointed a Director of the Clerical, Medical, and General Life Assurance Society, in the place of Sir Thomas Smith, Bart., F.R.C.S., deceased.

THE Honorary Membership of the Italian Society of Obstetrics and Gynaecology has been conferred on Dr. H. Macnaughton-Jones, President of the Obstetrical and Gynaecological Section of the Royal Society of Medicine, formerly University Professor of Obstetrics and Gynaecology in the Queen's University,

THE decision of Sir John Batty-Tuke, M.P., to retire from Parliament at the next election will create a vacancy in the Unionist candidature for the representation of the Edinburgh and St. Andrew's Universities. Sir John's services to the medical profession have been many and valuable, and his retirement will be a great loss to that body, in whose interest he has always been an ardent and able defender.

# A CLINICAL LECTURE ON APPENDICITIS WHEN THE VERMIFORM APPENDIX IS A PELVIC ORGAN.

By JOHN BLAND-SUTTON, F.R.C.S. Eng.,

Surgeon to the Middlesex Hospital.

ALTHOUGH it is well known that the vermiform appendix is often a pelvic organ, this common variation in its position has not received adequate recognition from the clinical standpoint at the hands of the family physician, the surgeon, or the gynaecologist. From the patient's point of view it is of some importance.

Anatomical observations teach us that the tip of the vermiform appendix may occupy any position in the abdomen from the region of the gall-bladder to the floor of the pelvis, in which situation it may, and often does, rest on the rectum. When an appendix lying in relation with the gall-bladder perforates, it will cause symptoms which are very similar to those produced by perforation of a septic gall-bladder, the duodenum, or the stomach, especially in the pyloric region.

When an appendix lying behind the cæcum sloughs, the symptoms simulate those of a perinephric abscess. Before 1886 many post-cæcal appendix-abscesses were regarded and treated as perinephric abscesses, or as empyemata.

When the appendix hangs in the pelvis it is as liable to inflame and to slough as in any other situation; if the patient be a man it often causes puzzling symptoms, but if the patient be a woman the nature of the disease is often overlooked, even when an operation is performed.

In the days when acute appendicitis was not so readily appreciated as it now is, many believed this morbid condition to be uncommon in women. In 1900 I published some observations to show that appendicitis in its most acute form often occurred in women, but its effects were usually attributed to lesions of the internal reproductive organs, especially pyosalpinx. An acute appendicitis when the tip of the vermiform appendix is free in the pelvis simulates, not only pelvic cellulitis and abscess, tubal pregnancy, and pyosalpinx, but it will set up salpingitis and ovaritis.

Let me mention two striking cases illustrating this: (1) A nurse, æt. 30, came under my care, with a tumour on the right side of the pelvis as big as a cricket ball. She was very ill, and some who saw her suspected that the lump might be malignant. Coeliotomy was performed, and I succeeded in enucleating a rounded semi-solid mass from the right broad ligament which proved to be the ovary infiltrated with pus. After removing this lump I looked into the pelvis and saw a thing sticking up exactly like the toadstool known as the dog-stinkhorn (*mutinus caninus*). This happened to be the vermiform appendix, as thick as my forefinger. When the ovary and appendix were investigated in the laboratory, a pure culture of streptococcus was obtained from each. We satisfied ourselves that the trouble arose in the appendix, then perforation occurred and the infection spread to the ovary. This organ proved to be tuberculous, for giant-cell systems were found in it, but we failed to find tubercle bacilli.

(2) This is more remarkable. A spinster, æt. 30, was suddenly seized with acute pain in the pelvis, followed next day by a profuse vaginal discharge. The pulse became rapid, the temperature rose to 103° F. A rounded, tender swelling could be easily felt on vaginal examination in the right half of the pelvis. The physical signs and symptoms pointed strongly to a pyosalpinx. The conditions under which the patient lived were not in favour of the common cause of acute pyosalpinx, and her general condition did not support the idea of an acute tuberculous salpingitis. An operation was advised and carried out: the Fallopian

tube was as thick as a thumb, and the vermiform appendix adhered by its terminal segment to the cœlomic ostium of the tube. With the exercise of a little care, I succeeded in removing the appendix, tube and ovary without disturbing their relation to each other. When these parts had been carefully hardened, I was able to demonstrate that the tip of the vermiform appendix had adhered to the mouth of the Fallopian tube, and that part of the appendix which was in relation with the tubal ostium had become perforated by ulceration, the infective fluid passing directly into the lumen of the tube causing acute salpingitis. As I have already mentioned, the symptoms and clinical signs in this patient were those set up by a leaking pyosalpinx.

The leading signs of acute appendicitis may be summarised thus:—Severe pain of sudden onset in the right iliac fossa, followed by acceleration in the pulse rate, and an increased temperature, which may amount to 103° or even 105° F., accompanied by great tenderness and an ill-defined swelling over the painful area, and the absence of rigors. When these signs are present, there is little fear of the nature of the condition being overlooked, certainly not by the doctor, and as the disease is so prevalent, especially in the inhabitants of large cities, the patients often recognise the disease without medical aid.

In cases of acute appendicitis, when the appendix lies in the cavity of the pelvis, there will be sudden pain followed by high temperature, and, as a rule, an acceleration of the pulse. The pain and tenderness will be localised to the hypogastrium, and the usual tumidity in the iliac fossa is absent. Such conditions are often attributed to other causes than appendicitis, and the "diagnostic doubts" will vary according to whether the patient is male or female. The least complicated of these cases arise in males. The following case will serve as an illustration, and indicate the great danger such patients run when the signs are mis-read.

(3) A man of middle age was admitted into a medical ward on account of severe and sudden abdominal pain. The patient appeared to be gravely ill, with rapid pulse, temperature 101° F., and the abdomen flat, but rigid. The hypogastric region was tender to the least pressure. The physicians were puzzled. They recognised that there was some grave lesion in the abdomen, but were uncertain of its nature and situation. Moreover, they could not make up their minds in regard to surgical intervention, and invited me to guide them. I recognised that the man was in all probability suffering from perforation of a pelvic appendix, and, acting on this opinion, I opened the abdomen by a median sub-umbilical incision, evacuated the pus, and removed a sloughing pelvic appendix. The patient left for a convalescent home in 21 days. This is by no means an uncommon case.

(4) A priest, æt. 39, had been ill three weeks on account of pain in the hypogastric region, accompanied by fever, painful defæcation, and frequent micturition. On rectal examination I could feel an indefinite hardness on the right side of the rectum, and came to the conclusion that he had a sub-acute appendicitis connected with a pelvic appendix. On opening the abdomen in the middle line, access to the pelvis was retarded by adherent coils of small intestines. These were carefully unravelled, and the vermiform appendix was discovered on the floor of the pelvis, lying between the rectum and the bladder, surrounded by a coil of ileum, and embedded in caseous pus. It required some care to avoid injuring the ileum

during the process of separating the adhesions. The appendix was removed, and drainage resorted to for a week. The patient made an excellent recovery. It was thought that the tubercle bacillus might be the cause of the trouble, but we failed to find it.

In some instances it is possible to diagnose acute appendicitis when the appendix occupies the pelvis, even in women.

(5) Dr. Guy Hollings asked me to see a girl, æt. 17, on account of sudden pelvic pain followed by the usual signs of a perforated viscus. He came to the conclusion that the cause of the trouble was perforation of an appendix lying in the pelvis, for, on a rectal examination, an indefinite tender mass could be felt involving the rectal wall on the right side of the pelvis. The condition was explained to the parents, and 16 hours after the onset of acute symptoms the abdomen was opened through a median sub-umbilical incision, and a sloughing vermiform appendix was found and removed, with good consequence to the patient. On three occasions Dr. Guy Hollings has detected acute appendicitis in a pelvic appendix, and in each case I have proved his diagnosis to be correct in the course of an operation, and all the patients recovered.

The intimate relation which exists between the tip of the vermiform appendix and the rectum, when the former hangs in the pelvis, explains one mode by which the disease tends to spontaneous cure. The following is not an uncommon taunt hurled by conservative physicians at radical surgeons: Tell us what happened to patients with acute appendicitis in the days antecedent to its surgical treatment? So far as the patients with a pelvic appendix are concerned, the answer is not difficult. When the wall of the appendix sloughs, a small quantity of highly infective fluid escapes into the cavity of the true pelvis; this fluid contains pathogenic micro-organisms, usually the common colon bacillus or the virulent streptococcus. In response to this irritation, the pelvic peritoneum exudes lymph very freely, and in the course of a few hours three or four ounces of thin, purulent, and often foetid fluid accumulates in the pelvis. It is important to appreciate this. I am an ardent advocate for resorting to surgical measures as soon as it is fairly certain that a patient has a perforated appendix, and it frequently happens that the physician in charge of the case will often express astonishment that so much pus could form in the course of a few hours after the signs of perforation had declared themselves.

When this purulent fluid forms abundantly, it will float up the small intestines and the adjacent omentum so that they form a roof to this collection of fluid, and for a time isolate it from the general peritoneal cavity. If the infecting micro-organism is of moderate virulence, the patient exhibits signs of a pelvic abscess, and in the course of a few days the purulent material will erode a hole into the wall of the rectum and escape through the anus. In some instances it will find a way out through the wall of the bladder or the vagina. In my early days as a surgeon I have assisted the pus to escape through the walls of the rectum by a timely thrust with a scalpel.

In cases where the pus does not escape from the pelvis through hollow viscera, it will accumulate and completely fill the pelvic cavity, and then slowly make its way along the serous surface of the ascending or the descending colon and fill one or both loins. In this event it may be diagnosed as a peri-nephritic abscess. At this stage the disease has become sub-acute, but pus continues to accumulate, and reaches the region of the diaphragm, and now stands a chance of being detected as a subphrenic abscess, or causing a difference of opinion among those in charge as to whether the patient is suffering from a subphrenic abscess or an empyema. In a few rare instances pus and gas from an acute appendix abscess arising in the pelvis have passed upwards along the course of the left colon, perforated the diaphragm, involved the lung, and been expectorated. In a remarkable case of this kind, recorded by Barnard, a man expectorated pus and gas on several occasions, and finally recovered (Fig. 1). It is known for certain that the primary source of the pus was a perforated pelvic appendix, because in the early stage of the disease the abdomen was opened by a median incision, and an attempt made to drain the pelvic abscess, and this

enabled the surgeon to determine the position of the vermiform appendix.

I have long since satisfied myself that many of the cases in which an appendix perforates, and the pus infects the peritoneal cavity and destroys the patient's life in three or four days, the appendix either occupies the pelvis or lies on its brim. I am not unmindful of

FIG. 1.—A diagram to show the route of pus from an appendix abscess in the pelvis to the trachea (after Barnard).

the fact that such disastrous consequences depend on the nature of the micro-organism in the pus, and such rapidly fatal infections occur with the common colon bacillus as well as with the *streptococcus*.

Great difficulty in diagnosis is often caused by an appendix which lies on the brim of the pelvis, with its terminal half-inch dipping into the pelvic cavity. In such a case an inflamed or perforated appendix will cause a local swelling nearer the middle line than usual, and this will stimulate very closely a distended and inflamed Fallopian tube. On the other hand, an inflamed tube and ovary lying near the pelvic brim in an unmarried woman are very likely to be diagnosed as an inflamed appendix. The relation of the right Fallopian tube to the appendix is more intimate than many believe who have not closely studied this matter, and it is quite a common mistake for surgeons who, as a rule, are not well-informed in pelvic gynaecological conditions, to mistake the signs set up by the bursting or abortion of an early tubal gestation for an attack of appendicitis.

My attention was drawn to this matter some years ago in a forcible manner. I was asked to see a young unmarried lady on account of what was regarded as an attack of acute appendicitis. I had to confess that the symptoms were such as to make me believe that the patient was suffering from acute salpingitis, although the domestic surroundings were against such an opinion. When the parts were exposed in the course of the operation, the right tube, ovary, and appendix were mixed up in the pelvis as to make it doubtful which organ was the primary offender. I removed all three, and, after operation, on gently squeezing the tube, I saw suspicious-looking pus exude from the cœlomic ostium. On examining the vulva, similar pus existed in abundance. I wrapped the excised ovary, tube and appendix in a sterilised drape, and immediately conveyed them to Mr. Foulerton, who

not only identified the gonococcus in the pus, but succeeded in cultivating it.

On two or three occasions I have removed the right ovary, Fallopian tube, and vermiform appendix, which occupied an abscess in the pelvis, and found it difficult to decide whether the Fallopian tube or the appendix was the organ primarily concerned.

When dealing with cases in which there is doubt whether the source of the suppuration is the appendix or the Fallopian tube, I am sure it is a wise course to open in the middle line, for this route gives free access to each of these organs, and provides the most direct route for drainage. The most ineffective measure of dealing with an appendix abscess in the true pelvis, is an attempt to drain it through an incision in the right flank. On several occasions I have had women placed under my care with persistent sinuses left after the evacuation of a supposed appendix abscess. In dealing with them by means of a median sub-umbilical incision, I have found the sinus to lead into the sac of a pyosalpinx, and found the vermiform appendix normal. In one extraordinary case a girl had a supposed appendix abscess evacuated by a lateral incision; a persistent sinus and a faecal fistula were the sequelæ, and she remained a bedridden invalid for two years and six months. She came under my care, and, on opening the abdomen and inspecting the parts, I found a healthy appendix, but bilateral pyosalpinx. In order to remedy the conditions existing in the pelvis, I found it necessary to remove both tubes and ovary, as well as resect four inches of the sigmoid flexure and twelve inches of ileum. The cut ends in each instance were joined by a circular enterorrhaphy, and with success.

It has been my practice for several years in all cases suspected to be acute appendicitis, with absence of swelling in the right iliac fossa, to open the abdomen by means of the median sub-umbilical incision. I always deal with these conditions without delay, and remove the appendix if it be the source of trouble. In an ordinary lateral operation for acute perforative appendicitis, if I have any reason for believing that pus has found its way into the pelvis, I make a small median incision and introduce a drainage tube reaching to the floor of the pelvis, and I believe that many lives have been saved by this plan. I cautiously remove the fluid exudate with gauze, but never flush out the pelvis with water, and avoid introducing any kind of chemical re-agent.

In order to afford some idea of the frequency with which appendicitis occurs in connection with a pelvic appendix, I have had the cases occurring in my practice from January 1st to July 1st, 1909, a period of six months examined with the following result:—

The operation for the removal of the appendix was performed on 57 occasions. There were 14 cases of acute appendicitis. Among these were 8 instances in which the vermiform appendix occupied the pelvis, and was removed through a median incision. In some of the patients in which the appendix was removed in the quiescent stage through a lateral incision the organ occupied the pelvis.

Thus, from a careful consideration of the matter, I have come to the conclusion, founded on a study of my own cases, that the vermiform appendix probably occupies the pelvis in about 20 per cent. of patients who suffer from appendicitis.

The advantage of the median sub-umbilical incision when the appendix occupies the pelvis is obvious, for it affords direct access to the troublesome organ.

In bringing these remarks to a conclusion, I would like to add that there is much difference of opinion among surgeons as to the propriety of removing a vermiform appendix when acutely inflamed. I hold a very strong opinion on this matter. If my vermiform appendix inflames, I will have it removed within twelve hours, and I carry out these principles in my practice.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Professor A. Mathieu, M.D., Physician to the Paris Hospitals. Subject: "The Symptoms of Intestinal Stenosis."

## ORIGINAL PAPERS.

### NOTES ON AN APPARATUS FOR THE ADMINISTRATION OF ETHER BY THE PURELY OPEN METHOD.

By DR. R. H. HODGSON.

MR. PRESIDENT AND GENTLEMEN,—By your kind permission I have the pleasure of showing you an apparatus which I believe is as effective as it is simple in the administration of ether by the open method, by which I mean, that the patient is anæsthetised by ether and air without breathing a second time, the same air or ether. For I feel that the disfavour in which ether anæsthesia is held by many is almost wholly due to the want of recognition of the objectionable re-breathing. There can be little doubt but that patients who are anæsthetised by the closed, or partially-closed, methods are more or less poisoned by their own breath, and that the deaths attributed to ether should be, in reality, assigned to auto-genetic narcotic poisoning, which arrests the circulation in the capillaries of the lungs, whereas ether stimulates that circulation. We take great care that our ether shall be pure, yet, when we give it by any other method than the absolutely open method, we mix it with most irrespirable gases. In support of this opinion, I may point out that with the strictly open method I experienced none of the causes for anxiety inseparable from the administration of ether by the closed, or partially-closed, method, such as bronchitis, pleurisy, nephritis, etc., nor was there any struggling or excitement whilst going under or coming to. Ether, given in this manner, seems to me to be free from danger, no matter what the patient's condition, and, furthermore, by making ether the vehicle, I have been able to give by inhalation, the following drugs:—Camphor, hexamethylene tetramin, carbolic acid, red iodide of mercury, iodide of arsenic, formalin, hamamelis, creosote, perchloride of mercury, guaiacol and iodine, the fumes from many of which are ordinarily most deadly for inhalation purposes, but which may be inhaled with impunity through an apparatus such as I now show. Thus it will be seen that pulmonary tuberculosis may be directly attacked by almost any drugs in the very seat of its origin, and it is, therefore, only reasonable to conclude that with the help of the anæsthetist pulmonary tuberculosis may be arrested and destroyed with great certainty. Although I have, so far, limited the value of inhalation to the cure of tubercle of the lung, I do not mean that the treatment is useless in tubercle of other parts of the body, but that the lungs afford the most convenient evidence of its benefits. I have, with this apparatus, administered ether alone, or mixed with other drugs, in extreme cases of pulmonary phthisis with cavity and without, in general tuberculosis, in tubercle of the lung and kidney, in tubercular pleurisy and in advanced organic heart disease with dilatation and impending death. In all cases rapid improvement has followed, and no danger has been apparent. Consumptives taking ether in this way show rapid alleviation of their symptoms, the expectoration is reduced in quantity in a few hours, the cough is lessened, the temperature lowered, the sweats reduced in number and severity, the appetite marvellously improved, the desire for and assimilation of fatty foods correspondingly increased and the area of dulness perceptibly diminished. Another great advantage of treating pulmonary phthisis through the medium of ether inhalation is that it

(a) Read before the Section of Anæsthetics, Royal Society of Medicine, Nov. 5th, 1909.

leaves the healthy parts of the lungs in a state of hypertrophic compensation without producing emphysema. The fact that I have administered ether by itself, or in conjunction with other drugs, by this apparatus on upwards of 450 occasions leads me to think that in bringing this method before you I am not only showing a useful instrument, but am opening up a large field of work for anæsthetists, whereby pulmonary consumption can be rapidly and effectually dealt with and anæsthetists become the lung operators of the day, and their instruments will be made for the finest tempered drugs. The apparatus, though simple, has the following advantages over any other that I have seen:—All the air breathed must first pass through the drugs—no second breathing of the same air can take place. The quantity of ether necessary for a long operation is small—2 or 3 ounces. Freezing of the ether may partially take place in exceptional circumstances. The patient feels but little sensation of suffocation.

There is practically no struggling going under or coming-to, and no fear of hæmorrhage.

The lungs and bronchial tubes are not choked by viscid mucus.

The after-complications of ether administration do not arise.

There are no sponges or other media liable to become foul or to accelerate freezing.

The enormously increased power of assimilation of fatty foods and the rapid relief of congestion of the lungs by those subjected to ether suggests the treatment in cases of diseases of the pancreas and in pneumonia.

## TUBERCLE OF THE LACRYMAL SAC. (a)

By SYDNEY STEPHENSON, M.B., C.M.

NOT so very long ago, well within my own memory, tubercle was believed to account for few affections of the eye. Tubercle of the choroid and of the conjunctiva were, it is true, recognised, but both were held to be extremely rare.

The more refined our means become of diagnosing tubercle, the more frequent do we find it to be associated with, and the probable cause of, many affections of the eye. Indeed, it is no exaggeration to claim that no anatomical structure of the eye, with the single exception of the crystalline lens, may not upon occasion be affected by tuberculosis.

In my experience, lacrymal disease, more especially lacrymal abscess, is in children over a year old nearly always due to either tubercle or syphilis. The little girl I now introduce to your notice is suffering from tuberculosis of the lacrymal sac, still sometimes spoken of as though it were a very rare condition. As a matter of fact, although few such cases have been reported, yet I am satisfied that amongst children the condition is far from rare. The affection, in my experience, is often primary, a point in which it resembles tubercle of the conjunctiva, and differs from tubercle of the choroid. The history of the present case is, briefly, as follows:—

Jessie Lovell, æt. 10, first seen on September 9th, 1909, on account of a swelling at the inner corner of the left eye, believed by her friends to have resulted from the bite of a mosquito some six weeks previously. The evidence upon which this statement was based would not stand a minute's critical examination. A reddish and somewhat tender swelling, with two or three tiny holes in its

anterior surface, lay over the region of the lacrymal sac below the inner canthus of the left eye. The lump was situated below the tendo oculi, but a rounded swelling, evidently the distended fundus of the lacrymal sac, could be felt above that structure, and when pressure was exercised upon the sac, muco-pus passed through the fistulæ in the skin. The conjunctiva, ocular and palpebral, was free from changes, tuberculous or otherwise. There were nebulæ of each cornea, evidently the result of a former attack of eczematous (phlyctenular) keratitis. The left preauricular gland was palpable, and the glands on the left side of the neck were a little enlarged. In particular, a small hard, tender swelling could be made out in the thickness of the left cheek, and doubtless represented one of the groups of small glands in that region to which attention was first directed by Poncet, of Lyons.

For the rest, the child was said to have lost a little flesh lately, but no physical signs could be made out in the chest, the abdomen, or elsewhere. Phthisis was denied as regards the family.

The appearance and the indolence of the swelling made me suspect tuberculosis, and the modification of the cutaneous tuberculin test, as recently recommended by Lautier ("Répertoire de Pharmacie," February, 1909) was accordingly tried. A piece of wool, moistened with a few drops of tuberculin and covered with an impermeable dressing, was bound upon the skin of one arm. No reaction followed the application. Von Pirquet's scarification was then tried, and a positive result was obtained in forty-eight hours.

The present condition (after the disease has lasted for some two and a half months) is as follows:—A reddish swelling, the size and shape of a coffee bean, lies over the left lacrymal sac, and is obviously connected with the latter. The skin is affected, and on pressing over the fundus of the lacrymal sac above the tendo oculi, muco-pus escapes through two or three tiny fistulæ in the swelling. Slight glandular enlargement on the left side of the neck. General health good.

### DIAGNOSIS.

We have gone some way in the direction of diagnosis when we recognise that such an affection as tubercle of the lacrymal sac exists. The tuberculous nature of a lacrymal affection may be inferred from the family history and co-existing signs of tuberculosis. A sign of value is an indolent enlargement of one or more of the glands contained within the thickness of the cheek, first described by Poncet, of Lyons. There are three groups of these small glands: (1) Supra-mandibular; (2) buccinator; (3) superior maxillary. The group last-named is the one usually enlarged in tuberculosis of the lacrymal sac. It is described by Trendelenburg (THE MEDICAL PRESS AND CIRCULAR, February 3rd, 1904) as "consisting in glands included in the naso-labial fold on a level with the lower border of the orbit at the internal palpebral angle." The adenitis rarely exceeds the size of a pea. The preauricular gland usually participates, and so do the submental and neighbouring glands. In one of my cases tubercle of the lacrymal sac (confirmed bacteriologically) was associated with massive enlargement of the corresponding preauricular gland and at a later stage of the cervical glands.

The tuberculous nature of a lacrymal affection can be demonstrated by the discovery of the tubercle bacillus in discharge from or scrapings from the affected sac. It is a very tedious business, and, indeed, it is often impossible to discover the micro-organisms in the discharge, although upon occasion I have succeeded in doing so. On the other

(a) Remarks based upon a Clinical Demonstration given at the Polyclinic, London, W.C., on October 8th, 1909.

hand, it is much simpler to examine scrapings from the interior of the diseased sac. It is a good plan to wash the scrapings with several lots of distilled water, so as to free them from blood, and then to select a suitable morsel, cut it across with fine scissors, and to smear the freshly-cut surface over several cover-slips. By these means I succeeded in demonstrating tubercle bacilli in the sac from a lad, æt. 9, who had had enlarged glands removed from his neck, and who presented coincident ulceration, believed to be tuberculous, of his nasal chambers. The case was reported in the "Reports of the Society for the Study of Disease in Children," Vol. V., 1905, p. 184.

The presence of tubercle elsewhere, supposing the sac mischief to be secondary, or in the sac itself, supposing the mischief to be primary, can be demonstrated by Calmette's ophthalmo-reaction, Moro's inunction, Von Pirquet's cutaneous test, or one of the other methods nowadays in current use. If the evidence of tubercle is strong, and yet no reaction follow the use of one or other of these tests, a second application should be made, or the method be changed, for example, from the Lautier skin application, as in the present case, to the Von Pirquet inoculation.

The local condition of the sac and overlying parts often affords presumptive evidence in favour of a tuberculous character. Indeed, as in the present case, its very appearance is suggestive of tuberculous lesions in other parts of the body. It is apt to show one or several fistulæ, and to feel not only thickened, but also "lumpy," as though it contained so many polypi, and such may actually be found after the surgical removal of the diseased sac. Persistence in an almost unchanged form for months together is also a characteristic of the cases,

#### TREATMENT.

If possible, the patient should be sent to the country or seaside; life in the open air should be insisted on, and cod-liver oil should be given internally. A remedy that is well worth trying in these cases is bismuth paste, compounded in accordance with E. G. Beck's formula (*Zeits. f. Chirurgie*, 1908, No. 18), which is as follows:—Bismuth subnitrate, 30; white vaseline, 60; soft paraffin, 5; and wax, 5. A small quantity of this compound should be injected into the lacrymal sac two or three times a week through one of the fistulæ that are usually present, or through the lower punctum lacrymale, previously dilated for the purpose. The bismuth paste should also be kept constantly applied to the affected part by means of a dressing. Another excellent application is iodoform emulsion.

If a change to the seaside or country be impossible, as it often is in poor London children, and the condition shows no signs of improvement under the measures described above, it is best to excise the lacrymal sac and any affected skin. The operation is by no means so simple as might appear, since the disease has not infrequently spread beyond the sac and caused more or less extensive adhesions to neighbouring parts. Quite an extensive dissection may then be required. Any serious difficulty in closing the wound, after removal of the sac, may be met by transplanting a piece of skin and subcutaneous tissue from some other part of the patient's body.

THE report of Dr. F. St. George Mivart to the Local Government Board on the General Sanitary Circumstances and Administration of the Borough of King's Lynn, has just been published, and can be purchased through any bookseller or from the Government publishers.

## HYPERTROPHIC CIRRHOSIS AND ALCOHOLIC PARALYSIS.

By H. C. DRURY, F.R.C.P.I.,

AND

A. C. O'SULLIVAN, F.R.C.P.I.

A—B—, was a large, stout woman, æt. 42. She had had 20 pregnancies, with 13 living children and seven mishaps, these latter having been irregularly distributed between the live births. There was no history or evidence of syphilis. She was admitted to hospital in a state of alcoholism, and there was a history of alcoholic habits. She complained of weakness and feeling of "pins and needles" in the feet and hands. There were abrasions on both knees from "her legs having given under her" on getting out of bed. Her mind was quite clear. The lungs were healthy. The heart-sounds were strong and regular, but there was a mitral systolic murmur; there was not, however, any evidence of failing compensation of the heart. Her temperature was 101° F.

On examining the limbs it was found that she could move the arms and hands well and extend the hand back to the full, but this power was found to be decidedly weak and the extension was overcome by very little force. The muscles of the arms, particularly the extensors, were painful to pressure. Similarly, she could flex the foot, but this movement was also weak; the muscles of the back of the legs were very painful to pressure, and any attempt to flex the foot caused great pain in the calf muscles. No reflexes could be obtained. Sensation was present, but various abnormal sensations were complained of. It was evident she was in an early stage of peripheral neuritis. This gradually developed from day to day till there resulted complete drop-wrist and drop-foot—she could draw the legs up in bed but could not extend them again.

The abdomen was of very large size and pendulous. At the umbilicus was a tumour about the size of a hen's egg which was the empty thickened sac of a long-standing umbilical hernia. The liver was greatly enlarged. There was also considerable enlargement of the spleen. There was no ascites. Jaundice was present, the conjunctiva being of a bright yellow colour, but the colouration of the skin was so slight that it might easily escape notice. The urine was high coloured, clear, without albumin or sugar, faintly alkaline to litmus paper, and a drop of acetic acid brought down a cloud of urates; it gave the iodine reaction for bile—the green colour being readily obtained and distinct, though not deep. The fæces were lighter than normal, but contained bile colouring matter and were not china-clay like.

The liver was very large, reaching in the parasternal line more than two handbreadths below the lower border of the ribs; this was not due to displacement downward, as the upper limit of liver dulness was at the normal level. The liver could be readily made out by palpation without percussion, and felt smooth on the surface, retained the normal shape of the organ and was very firm, the margin feeling sharp and hard. It was painless.

Simple hypertrophy was excluded by the great size of the organ, the jaundice and the absence of usual concomitants. Simple fatty liver was excluded by the extreme firmness of the organ and the remarkable sharpness of the edge, and also the liver was larger than one was likely to find in simple fatty liver. Amyloid liver was excluded by the absence of any cause for such, as there was no sign of there having been old-standing suppuration or syphilis, and the history of the pregnancies was alone sufficient to exclude this.

while, though the spleen was enlarged, there was no evidence of renal amyloid disease. The painless condition, great enlargement and absence of cardiac symptoms excluded congestion. All the symptoms and signs, however, supported the diagnosis that was made of hypertrophic or biliary cirrhosis, with the accidental accompaniment of alcoholic neuritis.

As the days passed the jaundice did not materially increase. She had continuous, but quite irregular febrile temperature for a time. After five days (10th October); she suddenly got profuse diarrhoea without any assignable cause, the only medicine she was taking being small tonic doses of quinine, which was immediately stopped. The diarrhoea continued uncontrolled, in spite of opium, for seven days, and then stopped, apparently under the influence of lead and opium pill. This attack of diarrhoea caused a great change in her condition. She became rapidly and alarmingly weak, and fell into a heavy lethargic or semi-comatose condition, but complained greatly of sleeplessness and a condition like nightmare. The sleeplessness did not yield to hypnotics. The heart-sounds became so weak that the murmur, which was at first loud, could not be heard.

The temperature fell to sub-normal, more a collapse temperature than a normal afebrile condition. With the increasing neuritis she became quite helpless, and so gradually sank lower, till she died rather suddenly on the 24th October.

The great enlargement of the liver having the characters already described, with enlarged spleen, with jaundice and without ascites; the irregular febrile temperature, profuse diarrhoea, bile-coloured faeces, great asthenia passing into semi-coma and death produce the clinical picture described by Hanot, which has been named Hypertrophic, or Biliary, or Insular Cirrhosis of the Liver.

#### **PATHOLOGICAL REPORT**

BY

A. C. O'SULLIVAN, F.R.C.P.I.

Liver weighed 7 lbs. 11 ozs. The increase in size was fairly uniform in both lobes, but was much greater antero-posteriorly than from side to side. Capsule somewhat thickened, finely granular on surface—light greenish yellow in colour. On section the connective tissue was seen to divide the liver up into small areas about as big as, or smaller than, a lobule under microscope. There was a great quantity of connective tissue arranged on the whole, with a tendency to surround lobules. It also sent delicate strands everywhere in between the liver cells. There was extensive fatty infiltration, and the liver was stained green in places with bile pigment. The connective tissue outside the lobules contained great quantities of newly-formed bile ducts.

The external cutaneous nerve showed an extensive degeneration, all the larger fibres being degenerated, myelin and axis cylinders broken up, and the nuclei of the sheath increased.

## **OPERATING THEATRES.**

### **ST. THOMAS HOSPITAL.**

**TWO RENAL CASES.**—MR. BATTLE operated on two renal cases, in both of which the symptoms had been rather severe, and in which it was difficult to make an exact diagnosis without the aid of the X-rays. The first was that of a woman, æt. about 30, who had suffered for some years from pain in the left side of the abdomen and back, which pain had occasionally been very severe, and accompanied by dark-coloured urine, apparently from the presence of blood in it. In

this case the pain, from the patient's description, had resembled very closely the pain of renal colic, but as the kidneys were movable on both sides, it was thought advisable to have an X-ray examination and ascertain whether a stone was present or not. Dr. Greg reported that nothing abnormal could be ascertained on examination with the X-rays; it was therefore concluded that this was a case of movable kidney with crises. At the operation the usual oblique incision was made in the left lumbar region, the kidney isolated from its bed and brought on to the loin. No stone could be felt either before or after the viscus had been brought up, but the central part of the convex border was softer than natural and depressed compared with the other parts of the kidney. It was evident that in this part there was a condition of partial hydronephrosis. The kidney was replaced in its normal position and the wound closed, without drainage. It had been considered, Mr. Battle said, that the kidney would contract adhesions in its bed, which would hold it firmly in position in the same manner as we see following a similar procedure in other cases of movable kidney.

The second case was that of a boy, æt. about 15, who had suffered from attacks of renal colic, with the passage of blood at intervals of about two years. Nothing abnormal could be found on examination of the kidney region, although there was a trace of blood in the urine. In this case, Dr. Greg reported that there was a shadow in the kidney, which he considered was caused by a small calculus. The usual incision was made to expose the kidney, and it was examined in front and behind with the finger, but it did not present any abnormality. When brought up on to the loin its appearance was that of a healthy kidney, but no stone could be felt. An incision was therefore made in the convex border, and the finger introduced into the pelvis. In one of the calices of the lower part a stone could be detected; this was removed. It was a flat, dark-coloured stone, shaped very much like a terminal phalanx of a finger. It was thin, like a flake of necrosed bone in appearance, but at the angles of its base, whitish oxalate crystals were clustered. The amount of bleeding from the incision into the kidney was very slight, and easily arrested by catgut sutures, which were passed transversely across the kidney substance at intervals of about half-an-inch. The kidney was replaced in its bed; a small drainage tube placed in the posterior part of the wound, and the wound closed with sutures placed in the lumbar fascia over the muscles and skin.

Mr. Battle considered that these cases showed the great utility of the X-rays in diagnosis of renal calculus. Although the stone in the second case was a small one, it threw a distinct shadow, and his experience was that when such a shadow was detected by this means a stone was present, but when there was no shadow there was no stone. Many cases of movable kidney had attacks of pain "crises," in which there was renal colic almost indistinguishable from similar attacks produced by stone. Operation proved the absence of stone, but frequently a hydronephrosis was discovered of a partial nature. Cure almost invariably followed operation, for the kidney contracted firm adhesions which prevented its falling again into the position which had produced that kinking of the ureter on which the attacks of pain depended. As a rule, attacks such as those met with in the first case quickly subsided, when the patient laid down for a time, but sometimes they were more persistent, and their occurrence made it necessary to operate, as, without relief, life was sometimes rendered rather a burden. In addition, the partial intermitting hydronephrosis might develop into a permanent general hydronephrosis, and the kidney be deprived of all usefulness.

In their efforts to advance the knowledge of child life, the Child-Study Society have secured the aid of Professor Karl Pearson, of University College, London, who has drafted a schedule for studying the factors that influence the social life of the child.

**SPECIAL REPORTS.****GENERAL MEDICAL COUNCIL.****NINETIETH SESSION.**

FIRST DAY.—TUESDAY, NOVEMBER 23RD, 1909.

The President, SIR DONALD MACALISTER, in the Chair.

DR. JOHN DIXON MANN, whose appointment as the representative of the Victoria University of Manchester was read to the Council on May 28th, 1909, was introduced by Dr. Caton.

The official notification of the appointment of Sir Christopher Nixon, Bart., M.D., LL.D., as representative of the National University of Ireland for a period of three years from November 11th, 1909, was read.

Sir Christopher Nixon was introduced by Sir Thomas Myles.

The PRESIDENT delivered the following address:—  
Gentlemen, His Majesty the King in Council has been graciously pleased to approve and give effect to the representations which, on May 25th, you directed to be made, and which I duly communicated to the Privy Council. An Order has accordingly been issued, which confers on the registered practitioners resident in England and Wales the power, at the next general election, of returning an additional member to this Council. Thus in about two years' time the directly elected representatives of the practitioners of England and Wales will number four, instead of three, as at present. Our respectful acknowledgments are due to the Privy Council for their good offices in commending our request to His Majesty's favourable consideration. After a few congratulatory words with reference to the baronetries conferred on Sir Henry Morris and Sir Dyce Duckworth, the President said the tragic death of Mr. Sydney G. Lushington, in the prime of his active powers, has deprived the Council of an adviser by whose legal skill and practical wisdom it has constantly profited during the past five years. Session by session Mr. Lushington gained an ever surer place in our esteem, not only for his professional but for his personal qualities. To his friends, and to the members of this Council which he served so well, his untimely death brings more than regret for the interruption of a distinguished career; it brings also a sense of sorrow as for a personal loss. As it was necessary to instruct Counsel to advise us with reference to certain penal cases, and to act as Assessor at inquiries to be held during the present Session, I consulted Mr. Muir Mackenzie and our solicitor, Mr. Winterbotham, on the subject. By their advice Mr. A. H. Bodkin has been requested to give us his assistance during this week. Mr. Bodkin is familiar with the procedure of the Council, and he holds a public legal appointment under the Attorney-General, similar to that previously held by Mr. Muir Mackenzie and Mr. Lushington. Before the end of this meeting I shall take occasion to ascertain your wishes as to future arrangements in this respect.

Another distinguished man, who for ten years was honourably associated with the Council as the direct representative from Ireland, has passed away during the present month. Sir William Thomson, C.B., had won a prominent place among his brethren for his manifold services to the profession and to the State. Those who sat with him in this chamber will long cherish the memory of his impressive bearing and his helpful interest in the Council's work. On your behalf I have sent a letter of condolence to Lady Thomson and her family.

We have to welcome, as a new member, Dr. John Dixon Mann, whom the Victoria University of Manchester sends to the Council in the place of Professor Young. He will find that his fame as a medical jurist has preceded him, and that the Council reckons with confidence on his ability to assist in dealing with the questions, partly medical, partly juridical, which come before it. He will find also that the associations left by Professor Young are of so happy a character that it is already a recommendation to be his successor.

We receive back Sir Christopher Nixon in a new guise, but with the old cordiality. In May he sat as the member for the Royal University of Ireland, of which he was Vice-Chancellor. The Royal University expired a few days ago, and with it his membership. But the National University of Ireland and the Queen's University of Belfast have now arisen in its stead. Sir Christopher returns with undiminished lustre as member for the National University, in which he is both Professor of Medicine and Vice-Chancellor.

Under recent Acts of Parliament the Queen's University of Belfast, and the University of Bristol, have each acquired the right to appoint a member of the Council. The Registrar has not yet received intimation that the appointments have actually been made.

The movement for the application to the Province of the Dominion of Canada of Part II. of the Medical Act, 1886, initiated in Nova Scotia and Quebec, continues to make progress. The Province of Prince Edward Island has now petitioned His Majesty in Council that the benefit of medical recognition, on reciprocal terms, may be extended to it. Negotiations on the question are proceeding, and as the Provincial law appears to afford due facilities for the local registration of all practitioners registered in the United Kingdom, it may be expected that a satisfactory agreement will speedily be reached.

A recent alteration in the Provincial law of Quebec appears to the Executive Committee to have the effect of limiting, in a manner which was not contemplated during the original negotiations, the recognition in Quebec of qualifications that are registrable in this country. As the question raised concerns in the first instance the Privy Council rather than the Medical Council, the attention of the Lord President has been called to it, and I have reason to believe that inquiries will be made through the proper official channels. We shall no doubt be informed of the result in due course.

The Committee appointed to consider various proposals for legislation on the subject of Anæsthetics were informed officially that no progress was likely to be made with these proposals during the present Session of Parliament. I therefore refrained from summoning the Committee to meet during the recess; but a meeting will be held during the present week, and a report on the subject will be prepared for your consideration. Meanwhile I was asked, as your President, to appear before a Departmental Committee, appointed by the Home Secretary, and give evidence regarding the action taken by this Council to promote the practical study of Anæsthetics by candidates for medical qualifications. I did so on November 19th, and laid before the Committee the relevant extracts from your minutes. The Chairman of the Committee expressed the desire that any further resolutions on the question, which the Council may adopt during the present Session, might be communicated to him.

The objections taken last May by the Council, on legal grounds, to certain provisions in the proposed draft charter of the British Medical Association, were communicated to the Lord President of the Privy Council for his information. There is reason to believe that our criticisms, and those offered by various other bodies, have been brought by His Lordship to the notice of the Association. It is probable that an amended draft, in which account is taken of these criticisms, will in due course be substituted by the Association for the original proposal.

The report of the Education Committee on the distribution of the medical students' time, as between the several parts of the curriculum, will in accordance with your resolution be discussed to-day. Its terms have been long before the Council, and have no doubt been carefully considered by members individually. It is to be hoped that the Council is now ready to discuss and to decide upon the important and yet simple proposals it contains for the improvement of medical education, more especially in regard to the branches of knowledge on which professional competence mainly depends.

The Pharmacopœia Committee held a two days' meeting last month, for the consideration of the suggestions for the revision of the Pharmacopœia.

made by the several medical authorities with respect in particular to the omission or inclusion of specified drugs and preparations. With the assistance of the Secretary, Dr. Tirard, the Committee were able to arrive at provisional conclusions in a large number of instances. These will form the basis for further inquiry, and at a later stage will come up for definite settlement. Meanwhile the Committee of Reference in Pharmacy continues its labours for the improvement, from a pharmaceutical point of view, of the several monographs in the present issue of the *Pharmacopœia*.

The November Session is understood to be set apart especially for disciplinary inquiries. Owing, perhaps, to the more systematic notification by the civil authorities of offences and convictions in which professional men are concerned, we have on this occasion a considerable number of such cases to deal with. Some of these are of a novel character, and will call for your special attention. But all have been patiently studied by the Penal Cases Committee, with the help of our Legal Adviser, and in the light of the documentary evidence submitted. In every instance the Committee has satisfied itself that there is a case which, *prima facie*, calls for an answer, and it has accordingly authorised the institution of an inquiry by the Council, before which alone the case and the answer can be fully stated and supported by oral or other testimony.

The question whether it is practicable in medical cases, as it is in dental cases, to delegate such inquiries, so far as the facts are concerned, to any body of members short of the full Council, has been occupying the attention of the Executive Committee. But in view of certain difficulties, as yet unsurmounted, the Committee are not at present prepared to offer definite proposals for your consideration. In so important a matter it is necessary that the statutory responsibilities of the Council should first be fully ascertained and discharged. Even serious considerations of convenience and economy cannot be allowed to outweigh considerations of legal obligation, should these prove to be in conflict. Personally, I express the hope that the Executive Committee may discover some way by which they may be reconciled.

Moved by Dr. LITTLE, seconded by Sir HUGH BEEVOR, and carried by acclamation: "That the President be thanked for his address, and requested to let it be printed in the minutes."

Moved by Dr. NORMAN MOORE, seconded by Sir HENRY MORRIS, and agreed to: "That the Council do adjourn at 4.30 p.m. to-day, to enable certain Committees to meet for the completion of their reports."

Moved by Dr. MCVALE, seconded by Sir JOHN MOORE, and agreed to: "That the table showing results of competition held in July, 1909, for Commissions in the Indian Medical Service, be received and entered on the minutes."

Moved by Dr. MCVALE, seconded by Sir JOHN MOORE, and agreed to: "That the thanks of the Council be conveyed to the Under-Secretary of State for India for the return which he has again furnished to the Council, with the request that such returns may in the future continue to be furnished to the General Medical Council."

Strangers having been re-admitted after the Council had considered certain matters *in camera* the President announced that the General Council had directed the Registrar to restore to the Dentists' Register the name of William MacGregor Veitch.

The Council resumed the adjourned consideration of the Education Committee's report on various proposals submitted to them referring to the curriculum in medicine, pursuant to the resolution of the General Council of June 1st, 1909, viz., that this business be taken on the first day of the November Session.

Moved by Dr. MACKAY, seconded by Sir CHRISTOPHER NIXON: "That the recommendation in the report of the Education Committee be adopted, viz.: That the following be added to the recommendations of the Council in regard to professional education:—For the purposes of this recommendation the subjects of the curriculum are arranged in two groups, the earlier group comprising the Preliminary Sciences and Anatomy and Physiology, the later group embracing

all the remaining subjects, exclusive of Pharmacy. The regulations of the bodies should be so framed as to secure (1) for the study of the subjects of the later group the reservation of a period equivalent in value to 2½ academic years (27 months) of undivided study, half-time value being allowed for periods of work in which studies in the earlier and later groups overlap; and (2) the reservation of a period of 2 academic years (24 months), in which the studies of the later group shall have the undivided attention of the student."

The CHAIRMAN of the Education Committee, Dr. MACKAY, dealt with the report in an interesting speech. A discussion followed, in which Sir John Fraser, Sir Hugh Beevor, Drs. Latimer, Finlay, and Norman Moore, Sir C. Ball, Sir T. Myles, Sir John Moore, Drs. F. Taylor, Saundby, and Kidd, Sir Henry Morris, Dr. Little, and Sir Christopher Nixon took part, the principal points under discussion being the time between the qualifying examination and the anatomical and physiological examination, also the system of blocking, taking up examinations piecemeal, and the preliminary course.

As the time had arrived for adjournment, it was moved by Dr. NORMAN WALKER, seconded by Sir CHRISTOPHER NIXON, and agreed to: "That the debate on the motion be now adjourned to a date to be fixed by the Business Committee."

The Council then adjourned.

SECOND DAY.—WEDNESDAY, NOVEMBER 24TH, 1909.

The President, SIR DONALD MACALISTER, in the Chair.

The minutes of the last meeting were taken as read and confirmed.

The Council proceeded to the consideration of the facts proved against Mr. William John Watson in regard to whom the Dental Committee, at its meeting on Monday, November 22nd, 1909, drew up a supplementary report.

The case was considered by the Dental Committee on May 25th, 1908, was further considered by the Committee on November 23rd, 1908, and was further considered by the Committee on May 24th, 1909.

At the close of the proceedings on May 28th, 1909, the President, addressing Mr. Watson, said:—

"Mr. Watson: The Council has again given careful consideration to the two reports of the Dental Committee, and has deferred the further consideration of your case to November next, when you will be required to be present in person, and to produce satisfactory evidence, and not merely a personal statement, as to your professional good conduct in the interval, with particular reference to your undertaking to discontinue all advertising, or connection, direct or indirect, with those who are advertising."

The President informed the Council that the Dental Committee had dispensed with the attendance of Mr. Watson from the present proceedings. He further stated that the other parties in the case did not desire to be heard in the further report.

The further report having been read, the Council deliberated on the case *in camera*. On strangers being re-admitted, the President announced that the Council had not directed the Registrar to erase from the Dentists' Register the name of William John Watson.

The Council proceeded to the consideration of the facts proved against Charles Morgan in regard to whom the Dental Committee, at its meeting on Monday, November 22nd, 1909, drew up a supplementary report.

At the close of the proceedings on May 28th, 1909, the President, addressing Mr. Morgan, said:—

"Mr. Morgan: The Council has again given careful consideration to the reports of the Dental Committee, and has deferred the further consideration of your case to November next, when you will be required to be present and to offer satisfactory evidence, other than your own statement, as to your professional good conduct in the interval, with particular reference to your promise to discontinue the issue, direct or indirect, of all advertisements."

The President informed the Council that the Dental

Committee had dispensed with the attendance of Mr. Morgan from the present proceedings. He further stated that the other parties to the case did not desire to be heard on the further report.

The further report having been read, the Council deliberated on the case *in camera*.

On strangers being re-admitted, the President announced that the Council had *not* directed the Registrar to erase from the Dentists' Register the name of Charles Morgan.

The Council considered the facts proved in the case of Thomas Torrens McKendry, registered as of 39, Wellwood Road, Goodmayes, Ilford, Essex, M.B., Bac. Surg., 1894, R. Univ. Irel., who had been summoned to appear before the Council at 2 p.m. on the following charge as formulated by the Council's solicitor:—

"That you have knowingly and wilfully on various occasions, and in particular on the 20th day of February, 1909, assisted one E. C. Dalby, a person not registered as a dentist, in carrying on practice as a dentist by administering anæsthetics on his behalf to persons coming to him for treatment, and that in relation thereto you have been guilty of infamous conduct in a professional respect."

The complainant was Mr. Victor Albert Chatelain.

At the close of the proceedings on Wednesday, May 28th, 1909, the President, addressing Mr. McKendry, said:—

"Mr. McKendry: The Council has postponed judgment till the November session, when you will be required to attend in person and to produce evidence, more particularly from medical colleagues in your neighbourhood, as to your professional good conduct generally in the interval, and in particular that you have not repeated the offence of which complaint has been made."

Mr. McKendry indicated in answer to his notice; he was not accompanied by counsel or solicitor.

Mr. Chatelain, the complainant, was not present, but the Council's solicitor read a letter from him, stating that he had no further evidence to tender to the Council.

Mr. McKendry tendered himself as a witness on his own behalf, and put in three testimonials as to character from medical practitioners, viz., from Mr. A. J. Pattison and Mr. H. W. Garden, of Goodmayes, and Dr. T. R. Atkinson, of Chadwell Heath. He also answered questions put to him by the Council's solicitor, and undertook not to administer anæsthetics for unregistered persons in the future.

After the Council had deliberated on the case *in camera*, Mr. McKendry and strangers having been re-admitted, the President announced the decision of the Council as follows:—

"Mr. McKendry: The Council have taken into consideration the evidence which you have produced, and does *not* see fit to direct the Registrar to erase your name from the Medical Register."

The Council considered the case of Robert Wiseman Cunningham, registered as of King's Island, Tasmania, M.B., Mast. Surg., 1895, M.D., 1904, Univ. Edin., who had been summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

"That you abused your position as a medical man by committing adultery and eloping with Alice Mary Wigram, whose husband you had been attending professionally and while you were the medical attendant of the family, of which adultery you were found guilty by the decree of the Probate, Divorce, and Admiralty Division (Divorce) of the High Court of Justice, dated June 11th, 1909, in the case of Wigram *v.* Wigram and Cunningham, in which you were the co-respondent, and that in relation thereto you have been guilty of infamous conduct in a professional respect."

Mr. Cunningham did not attend in answer to his notice, nor was he represented by counsel or solicitor.

The Council's solicitor read the notice, and, in the absence of a prosecutor, opened the case. He read the evidence given at the Divorce Court. He also read a letter which had been sent by Mr. Cunningham in answer to his notice.

Strangers then withdrew, by direction from the chair, in order that the Council might deliberate on the case *in camera*.

On strangers being re-admitted, the President announced the judgment of the Council as follows:—

"I have to announce that the Council have judged Robert Wiseman Cunningham to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase from the Medical Register the name of Robert Wiseman Cunningham."

The Council resumed the consideration of the Education Committee's report on various proposals submitted to them referring to the curriculum in medicine.

After a discussion, in which Drs. Norman Walker and Finlay, Sir Clifford Allbutt (who made an admirable and sensible speech), the President, Sir Henry Morris, and Dr. Saundby took part, it was moved by Dr. NORMAN MOORE, seconded by Dr. SAUNDBY, and agreed to:—

"That the debate be adjourned to a convenient opportunity."

The Council considered the case of John L'Estrange McGrane, registered as of Killucan House, Killucan, Westmeath, Lic. R. Coll. Surg. Irel., 1884, Lic. K.Q. Coll. Phys. Irel., 1885, who has been summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

"That, while holding the appointment of ship's surgeon on the s.s. *Trafford Hall* on her voyage beginning at Liverpool on June 22nd, 1909, and ending at Birkenhead, Liverpool, on September 18th, 1909, you were repeatedly drunk and incapable of performing the duties which as a registered medical practitioner you had undertaken to perform, and that on various occasions you were fined in respect of such dereliction under the regulations in force on the ship for maintaining discipline and were too drunk for the entries to be read over to you. And that in relation thereto you have been guilty of infamous conduct in a professional respect."

The original information upon which this charge is based was laid before the Council by the Board of Trade.

Mr. McGrane attended in answer to his notice, accompanied by Mr. George Wallace, his counsel, instructed by Mr. Reginald Hingston, his solicitor.

The Council's solicitor read the notice, and in the absence of any complainant, proceeded to open the case. He read a statutory declaration of Mr. Frederick Henry Southern, in the employment of the managers of the Hall Line of steamers, and extracts from the official log of the s.s. *Trafford Hall*.

He then called Mr. John Carey, from the office of the Registrar of Shipping, as a witness, and examined him. Mr. Carey also answered questions put to him by the Legal Assessor. He was cross-examined by Mr. Wallace.

Mr. Wallace then opened the case for the defence. He called Mr. Arthur D. O. C. Finegan, a registered medical practitioner, of Mullingar, as a witness, and examined him. Mr. Finegan was cross-examined by the Council's solicitor, and answered questions put to him by the Legal Assessor and by the Chair. He was re-examined by Mr. Wallace.

Mr. Wallace then called Mr. McGrane as a witness on his own behalf, and examined him. Mr. McGrane answered questions put to him by the Council's solicitor and by the Legal Assessor. He also answered questions put to him by the Chair and by members of the Council through the Chair. He was re-examined by Mr. Wallace.

Mr. Wallace called Mrs. McGrane, and examined her as a witness.

Mr. Wallace then addressed the Council on behalf of Mr. McGrane, and the solicitor addressed the Council in reply.

The Council then deliberated on the case *in camera*.

Mr. McGrane and strangers having been re-admitted, the President announced the judgment of the Council as follows:—

"Mr. John L'Estrange McGrane, I have to announce that the Council have come to the following decision in your case, viz., that the facts alleged

against you in the notice have *not* been proved to the satisfaction of the Council."

The Council proceeded to the consideration of the case of Alexander Riddle Stower, registered as of 80 Shaftesbury Avenue, London, W., "in practice before July 22nd, 1878."

The complainants were the British Dental Association.

The complaint, having been referred to the Dental Committee to ascertain the facts, the Dental Committee reported as follows:—

On November 23rd, 1909, the inquiry was held.

The said Alexander Riddle Stower attended personally, and was represented by Mr. Cannot, instructed by Mr. Angiers, solicitor.

The British Dental Association, the complainants, appeared by counsel, Mr. Hart, instructed by Messrs. Bowman and Curtis-Hayward, solicitors.

The Committee find that the following facts were established by the evidence:—

The said Alexander Riddle Stower was registered in the Dentists' Register on July 19th, 1879, as "in practice before July 22nd, 1878," and his address in the Register for the current year is 80, Shaftesbury Avenue, London, W.

The said Alexander Riddle Stower has advertised his professional practice:—

(a) By advertisements carried by two sandwich men parading Oxford Street.

(b) By the issue and circulation of leaflets and a calendar adorned with a female portrait, and

(c) By advertisements in the public newspapers describing himself as "Stower's Dental Association," and asking for agents.

(d) By various conspicuous notices on the front of 80 Shaftesbury Avenue, where he carries on his profession, consisting of notices in six windows, a swinging sign at the entrance, a show-case illuminated with electric lights, and other notices both outside and inside the premises.

These advertisements and leaflets are of a highly objectionable character.

The said Alexander Riddle Stower stated that some of the advertisements complained of had been withdrawn, and that it was not his intention to employ sandwich men or to advertise in the newspapers in future.

Mr. Stower now attended in answer to his notice, accompanied by Mr. E. H. Cannot, his counsel, instructed by Mr. C. A. Angier, his solicitor.

The British Dental Association, the complainants, were represented by Mr. Hart, counsel, instructed by Messrs. Bowman and Curtis-Hayward, their solicitors.

The report having been read, Mr. Cannot addressed the Council on behalf of his client. Mr. Hart addressed the Council in reply.

The Council then deliberated on the report *in camera*.

Mr. Stower and strangers having been re-admitted, the President announced the judgment of the Council as follows:—

"Alexander Riddle Stower: I have to inform you that on the facts proved in the report of the Dental Committee, it has been held that you have been guilty of infamous or disgraceful conduct in a professional respect, and that the Registrar be directed to erase from the Dentists' Register the name of Alexander Riddle Stower."

The Council then adjourned.

### THIRD DAY.—THURSDAY, NOVEMBER 25TH, 1909.

The President, SIR DONALD MACALISTER, in the Chair.

THE minutes of the last meeting were taken as read and confirmed.

The Council proceeded to the consideration of the case of Frederick Morrish Pierce, registered as Mem. R. Coll. Surg. Eng. 1867, Lic. Soc. Apoth. Lond. 1867, Lic. R. Coll. Phys. Lond. 1868, M.D., Q. Univ. Irel. 1868, now of 50 Gordon Square, W.C., who had been summoned to appear before the Council on the following charge as formulated by the Council's soli-

citor:—"That, being a certifying surgeon appointed by the Secretary of State under the Factory and Workshop Act, 1901, you, for the purpose of evading the conditions under which you were appointed, which required the personal fulfilment of the duties prescribed by the Act (except under the circumstances and on the conditions laid down in the instructions issued by the Secretary of State), knowingly and wilfully employed another registered medical practitioner (viz., Edward Arthur Burgess) to perform your duties; and that in order to carry out this system of evasion you committed the following offences, viz.:—

"(a) It being your duty as such certifying surgeon to examine young persons under 16 and children for certificates of fitness for employment in factories and workshops and to grant certificates in suitable cases, you allowed the said Edward Arthur Burgess to conduct the examination for you and to sign your name to certificates that you had personally examined certain persons on certain dates named, and that they were fit to perform the work on which they were engaged.

"(b) It being your duty as such certifying surgeon to investigate and report upon certain accidents, you allowed the said Edward Arthur Burgess to visit the works and the injured persons for you, and you thereafter signed certificates that you had personally investigated the causes of such accidents and had personally taken the evidence of such injured persons, when, in fact, you had made no such personal investigation and had not personally taken such evidence, but the certificates were subsequently filled up by you upon information furnished to you by the said Edward Arthur Burgess.

"(c) It being your duty as such certifying surgeon personally to examine and certify persons employed in certain dangerous processes, you allowed the said Edward Arthur Burgess to examine such persons on your behalf and to insert the necessary particulars in the Health Register, which you afterwards signed; and in other cases you signed the said Register in advance, the necessary particulars being afterwards filled in by the said Edward Arthur Burgess when he visited on your behalf.

"And that in relation thereto you have been guilty of infamous conduct in a professional respect."

The original information on which this charge was based was laid before the Council by the Home Office.

Dr. Pierce did not attend in answer to his notice, but was represented by Mr. Thomas Penson Griffiths, of Messrs. Chester, Broome, and Griffiths, 36 Bedford Row, London, W.C., his solicitor.

Mr. Griffiths stated that Dr. Pierce was too unwell to appear before the Council, and read a medical certificate to that effect from Mr. John Galley Blackley, M.B., M.R.C.S., of 29 Devonshire Place, London, W., dated November 24th, 1909, and a telegram, dated November 25th, 1909, to the same effect.

The Council's solicitor read the notice, and, in the absence of a complainant, opened the case, and referred to certain entries in the Health Register of Messrs. Charles Macintosh and Co., Limited, Manchester; in a register of persons, under 16 years of age, certified fit for employment by Messrs. Bannerman; and in reports as to injured persons. He also referred to letters written by Dr. Pierce. He then called Dr. B. Arthur Whitelegge, C.B., H.M. Chief Inspector of Factories, and examined him as a witness. Dr. Whitelegge was cross-examined by Mr. Griffiths, and answered questions put to him by the Legal Assessor. He was re-examined by the solicitor, and answered further questions by Mr. Griffiths and the Legal Assessor; he also answered questions put to him, through the Chair, by members of the Council.

The Council's solicitor then called Mr. James Edward Ashworth, H.M. Inspector of Factories in charge of the Manchester district, and examined him as a witness. Mr. Ashworth was cross-examined by Mr. Griffiths, and answered questions put to him by the Legal Assessor and by the Chair.

The Council's solicitor called Mr. Edward Arthur Burgess, L.S.A., M.R.C.S., and examined him regarding his declaration and the correspondence exhibited thereto. Mr. Burgess was cross-examined by Mr.

Griffiths, and also answered questions put to him from the Chair.

Mr. Griffiths put in a statement by Dr. Pierce in answer to the notice, which he read. He then addressed the Council on behalf of Dr. Pierce.

The Council's solicitor addressed the Council in reply.

After the Council had deliberated on the case *in camera*, strangers having been re-admitted, the President announced the judgment of the Council as follows:—

"Mr. Griffiths: I have to announce that the Council have judged Frederick Morrish Pierce to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase from the Medical Register the name of Frederick Morrish Pierce."

The Council next considered the case of Robert Orr, registered as of Ceres, Fifeshire, M.B., Bac. Surg., 1901, Univ. Glasg., who had been summoned to appear before the Council on the following charge as formulated by the Council's solicitor:—

"That you were, on October 1st, 1907, convicted at the Sheriff Court of Fife at Cupar of the following offence, namely, of assaulting a constable of the Fifeshire Constabulary, while engaged in the execution of his duty. And that you were on July 6th, 1909, convicted of the following offence, namely, of breach of the peace and of assaulting James Arthur, Helen White or Arthur, Catherine Dempsey or Kerr, and Catherine Quin."

Mr. Orr attended in answer to his notice; he was not attended by counsel or solicitor.

The solicitor read the notice and the two certificates of conviction.

Mr. Orr then addressed the Council on his own behalf. He did not tender any witnesses.

After the Council had deliberated on the case *in camera*, strangers having been re-admitted, the President announced the decision of the Council as follows:—

"Mr. Orr: The Council have given careful consideration to the question of your convictions and the circumstances connected therewith, and have decided to postpone judgment thereon till the May Session, when you will be required to be present, and it will be in your interest to produce on that occasion testimony from persons of position in your own neighbourhood as to your character and conduct in the interval."

The Council then adjourned.

#### FOURTH DAY.—FRIDAY, NOVEMBER 26TH, 1909.

The President, SIR DONALD MACALISTER, in the Chair.

THE minutes of the last meeting were taken as read and confirmed.

The Council resumed the adjourned discussion on the Education Committee's report.

The discussion was carried on by Mr. Hodsdon, Prof. Thomson, Drs. Knox, Taylor, Latimer, McVail, McManus, Adye-Curran, Caton and Mann, the general feeling being against any further lengthening of the curriculum.

Dr. MACKAY then responded, and, with the consent of his seconder, withdrew his motion and obtained leave to substitute the following: "That the regulations should be so framed as to ensure that the study of the Final Group of subjects should extend over not less than two and a half academic years after the passing of the examination in Anatomy and Physiology has been passed."

An amendment was moved by Sir HENRY MORRIS, seconded by Dr. NORMAN MOORE: "That the regulations should be so framed as to ensure that the study of the Final Group of subjects should extend over not less than two years after the passing of the examination in Anatomy and Physiology has been passed."

The amendment was carried, and, being put as a substantive motion, was also carried.

Moved by Dr. MACKAY, seconded by Dr. NORMAN WALKER, and carried: "That the two years in the preceding motion be defined as twenty-four months."

Sir Henry Morris sought leave to move a resolution which had not been placed upon the programme of business. Leave was accorded. Moved by Sir HENRY MORRIS, seconded by Dr. LANGLEY BROWNE, and carried: "That it be referred to the Education Committee to consider further the place in the student's career which the preliminary sciences should occupy, and that the Committee be requested to frame and submit to the Council a pattern scheme of medical education whereby the required minimum of the several subjects to be included in the curriculum can be adequately studied and the requisite examination thereon passed, by the average student, within the period prescribed by the curriculum."

For, 17; against, 5; 10 did not vote; absent, 2.

Strangers then, by direction from the Chair, withdrew in order that the Council might receive *in camera* a report from the Executive Committee with regard to penal procedure.

The Council next proceeded to the consideration of the case of Charles Frederick Dillon Shaw-Mackenzie, registered as c/o Messrs. Duncan and Duncan, solicitors, Dingwall, M.B., Mast. Surg. 1885, Univ. Edin., who had been summoned to appear before the Council on the following charge as formulated by the Council's solicitor: "That you were, on February 8th, 1909, convicted of the following misdemeanour at the Petty Sessions at Whitby, in the County of York, namely, of being unlawfully guilty, while drunk, of disorderly behaviour at Ruswarp. And that you were, on January 25th, 1909, convicted of the following misdemeanour at the Petty Sessions at Wigton, in the County of Cumberland, namely, of being drunk and incapable in Eden Street, Silloth."

Mr. Shaw-Mackenzie was called, but did not answer to his notice, nor was he represented by counsel or solicitor.

The Council's solicitor read the notice and two certificates of conviction. In the absence of Mr. Shaw-Mackenzie, the solicitor read letters from him dated respectively June 5th, 1909, in answer to a request for an explanation, and November 22nd, 1909, in answer to his notice.

The Council deliberated on the case *in camera*. Strangers having been re-admitted, the President announced the decision of the Council as follows: "We have to announce that the Council has found that Mr. Charles Frederick Dillon Shaw-Mackenzie has been found to have been convicted of the misdemeanours alleged against him in the notice of inquiry, and that the Council have decided to postpone judgment thereon till the May Session, when he will be required to be present, and to produce on that occasion testimony from persons of position as to his character and conduct in the interval."

The Council considered the case of William Shaw, registered as of Larne, Co. Antrim, Lic. R. Coll. Phys. Edin. 1886, Lic. R. Coll. Surg. Edin. 1886, who had been summoned to appear before the Council on the following charge as formulated by the Council's solicitor: "That you were convicted on March 24th, 1909, and again on March 23rd, 1909, at the Larne Town Court of being found drunk in a public street, and on August 24th, 1909, at Larne Petty Sessions of the following misdemeanour, namely, of being found on licensed premises in contravention of the provisions of the Licensing Acts."

Mr. Shaw did not answer to his notice, nor was he represented by counsel or solicitor.

The Council's solicitor read the notice and the certificates of conviction. He also stated that notice had been received of a further conviction and a summons against Mr. Shaw, judgment in which had been postponed. The solicitor read letters which Mr. Shaw had written in answer to the request for an explanation, and in answer to his notice. A medical certificate from Samuel W. Hill, M.B., B.Ch., a further letter from Mr. Shaw dated November 20th, 1909, and a letter from Mr. John Campbell, M.A., M.D., F.R.C.S., asking that the Council would postpone action till the May Session, was also made.

The Council deliberated on the case *in camera*. Strangers having been re-admitted, the President announced the judgment of the Council as follows:

"I have to announce that William Shaw, having been proved to have been convicted of divers misdemeanours alleged against him in the notice of inquiry, the Registrar has been directed to erase his name from the Medical Register."

The Council considered the case of Harry Robert Emms, registered as of 132 Winson Green Road, Birmingham, Mem. R. Coll. Surg. Eng. 1896, Lic. R. Coll. Phys. Lond. 1896, who had been summoned to appear before the Council on the following charge as formulated by the Council's solicitor: "That you were, on June 16th, 1909, convicted at the Cambridge Borough Police Court of having, on May 29th, 1909, feloniously stolen a bicycle belonging to one Debendra Mohan Bose, and on June 7th, 1909, of having feloniously stolen a New Chesterton bicycle belonging to one Alfred Conway, and a Standard Triumph bicycle belonging to one Thomas James Mudd."

Mr. Emms was called, but did not answer to his notice, nor was he represented by counsel or solicitor.

The Council's solicitor read the notice and the certificate of conviction. There was no communication from Mr. Emms.

After the Council had deliberated on the case *in camera*, strangers having been re-admitted, the President announced the judgment of the Council as follows:—

"I have to announce that Harry Robert Emms, having been proved to have been convicted of the felony alleged against him in the notice of inquiry, the Registrar has been directed to erase his name from the Medical Register."

The Council considered the case of James Alexander Pettigrew, registered as of 11 Lowther Street, Whitehaven, Cumberland, "in practice before July 22nd, 1878," in regard to which the Dental Committee had found the following facts established by the evidence:—

That on January 4th, 1909, the said James Alexander Pettigrew was convicted at the Lancaster Quarter Sessions of unlawfully and wilfully neglecting certain children under the age of 16 years in a manner likely to cause them unnecessary suffering and injury to their health, and was sentenced to six months' imprisonment with hard labour.

Mr. Pettigrew did not answer to his notice, nor was he represented by counsel or solicitor.

After the report of the Dental Committee had been read, the Council deliberated on the case *in camera*. Strangers having been re-admitted, the President announced the judgment of the Council as follows:—

"I have to announce that James Alexander Pettigrew having been proved to have been convicted of the misdemeanours alleged against him, the Registrar has been directed to erase from the Dentists' Register the name of James Alexander Pettigrew."

Moved by Dr. SAUNDBY, seconded by Mr. HODSDON, and agreed to: "That the question of allowing candidates to enter for each of the subjects separately of the final examination in medicine, surgery, and midwifery be remitted to the Examination Committee for consideration and report."

Moved by Dr. McVAIL, seconded by Sir JOHN MOORE, and agreed to: "That the report of the Examination Committee on the returns as to examinations for the Services received since the last Session of the Council be received and entered in the minutes."

Moved by Dr. McVAIL, seconded by Dr. SAUNDBY, and agreed to: "That the report from the Examination Committee on the Final Examination of the Apothecaries' Hall, Dublin, held in January, 1909, be received and entered in the minutes."

Moved by Dr. McVAIL, seconded by Dr. SAUNDBY: "That the report from the Examination Committee on the Final Examination of the Apothecaries' Hall, Dublin, held in April, 1909, be received and entered in the minutes."

The following amendment was then moved by Dr. ADYE-CURRAN, and seconded by Dr. McMANUS: "That the report of the Final Examination of the Apothecaries' Hall of Ireland be further postponed till the May Session in order that the remarks of the body concerned may be added."

The debate on the amendment was adjourned. The Council then adjourned.

FIFTH DAY.—SATURDAY, NOVEMBER 27TH, 1909.

The President, SIR DONALD MACALISTER, in the Chair.

The Council resumed the consideration, adjourned from the previous day, of the reception of the report from the Examination Committee on the Final Examination of the Apothecaries' Hall, Dublin, in April, 1909, on which Dr. Adye-Curran had moved an amendment. It was agreed, when proposed by Dr. ADYE-CURRAN, seconded by Dr. LATIMER, that the correspondence from the Apothecaries' Hall, Dublin, should appear as an appendix to the report of the Examination Committee.

Dr. McVAIL, seconded by Dr. NORMAN WALKER, proposed that the report be adopted. After Dr. Adye-Curran had made some further remarks, Dr. McVail's motion that the report be adopted was carried: 19 for, 4 against, 4 did not vote, 7 absent.

The Council then considered the report of the Education Committee, with reference to an application from the Apothecaries' Hall, Dublin, regarding the recognition of its preliminary examination. The Committee had passed the following resolution: "That the application be refused, and that for the reasons the applicants be referred to the decision of the Council as reported in the minutes for 1894 and for 1903."

Dr. MACKAY, seconded by Mr. HODSDON, moved that the report be received, entered on the minutes and approved. Dr. Adye-Curran made some remarks in defence of the application, and, after a few explanatory words from the President, Dr. Mackay's motion was put and carried: 27 for, 1 against, 6 absent.

Mr. TOMES, seconded by Dr. KNOX, moved that the report of the Dental Education and Examination Committee be received, entered on the minutes and adopted. The report referred to an application from Mr. H. M. McNeill for dental registration, which had been made in January, 1909, on the ground that he possessed the L.D.S. diploma of New Zealand and the D.D.S. of the University of Toronto. As neither of these certificates has hitherto been recognised as entitling their possessor to registration, the application was refused. Mr. McNeill had appealed to the Privy Council. The present report was very long, and the Dental Education and Examination Committee went *in extenso* into their reasons for recommending the Council to reply to the Privy Council that in connection with this case they do not consider that the possession of the diplomas tendered affords "a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice of dentistry or dental surgery." The motion was carried.

Moved by Sir JOHN MOORE, seconded by Dr. BARRS, and agreed to, that the report of the Pharmacopœia Committee be received and entered on the minutes. The report had reference to improvements in the British Pharmacopœia and to the incorporation in it of the Indian and Colonial addendum.

The report of the Students' Registration Committee was received, and is to be entered on the minutes.

Moved by the PRESIDENT, seconded by Sir C. BALL, and agreed to, that the report of the Anæsthetics Committee be received and entered on the minutes. With regard to the adoption of the report, the President put all the conclusions one by one to the Council; they were all agreed to.

The Council adopted the recommendation of the English Branch Council for the registration of Mr. Alfred Alexander Donald McCabe-Dallas, who had been entitled to be registered under the Medical Act (1858), but who had neglected to effect such registration until after the "appointed day" (June 30th, 1887) under the Medical Act (1886).

Dr. NORMAN moved a vote of thanks to the President. This was carried by acclamation.

By request of the President, strangers then withdrew in order that the Council might deliberate *in camera*, before rising.

## TRANSACTIONS OF SOCIETIES.

## NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT SHEFFIELD, FRIDAY,  
NOVEMBER 19TH, 1909.

Dr. J. W. MARTIN (Sheffield), President, in the Chair.

Dr. DONALD (Manchester) read notes of a case of *Wertheim's operation for advanced cancer of the cervix*, which was followed by uræmia. Only four ounces of urine were passed on the first two days, and none at all on the third; on the fourth and fifth 62 and 120 ounces respectively were passed, and the patient appeared to be making good progress. On the sixth day coma set in, and death occurred a few days later. At the post-mortem examination the right kidney was found to be the seat of old cystic disease and to contain but little secreting tissue, whilst the left ureter had been constricted by a ligature. The left kidney was engorged, but appeared to have been healthy before the operation.

Dr. H. BRIGGS (Liverpool) recorded a case in which he had removed a *pyosalpinx*, on account of pelvic pain of a month's duration, from a ii.-gravida, who was two months pregnant. The operation was performed three weeks ago, and the pregnancy is apparently undisturbed. Dr. Briggs also gave the details of a case of old-standing left-sided *pyosalpinx*, for which the patient had refused operation three years previously. She improved and bore two children, but during the last nine months several attacks of pelvic pain had occurred. Recently the left ovary and the tube, which contained pus, had been removed.

Mr. PERCIVAL E. BARBER (Sheffield) read the notes of a case in which he had performed total abdominal hysterectomy for *placenta prævia centralis*. The patient, a iv.-gravida, had been losing for a week before admission to hospital. Vaginal examination caused profuse hæmorrhage, which necessitated plugging the cervix and vagina. When Mr. Barber saw the patient, she was blanched and apparently moribund; the pulse-rate was 140. The uterus, containing a dead full-time child, was removed, two pints of saline being, meanwhile, infused intravenously. The patient made a good recovery. The following specimens were shown:—

Dr. Lloyd Roberts (Manchester): A uterus which had been removed for *malignant disease of the corpus*. It was found to contain a fibroid polypus whose base was invaded by glandular carcinoma arising from the neighbouring endometrium. The apex of the polypus was quite free from malignant disease. The patient was a multipara of 65, who had ceased to menstruate at 50. For three months there had been almost constant hæmorrhage, with floodings, accompanied by severe pain, on three occasions.

Dr. J. E. Gemmell (Liverpool): A *sarcoma of the mesentery*, which clinically had simulated an ovarian cyst with long pedicle.

Dr. W. E. Fothergill thought the microscopical appearances were those of a perithelioma.

Mr. R. Favell (Sheffield): A round-cell *sarcoma of the vagina*, occurring in a single woman, æt. 25. The hard, nodular growth was easily enucleated, and removed with its covering of vaginal wall.

Mr. P. E. Barber: A full-time *ectopic gestation sac*, which had been successfully removed from a multipara, æt. 34. Soon after the commencement of the period of nine months' amenorrhœa, she had experienced a sudden attack of right-sided pelvic pain, with a feeling of faintness; this was not accompanied by external hæmorrhage. The fetal movements, which had been very violent and painful, had ceased six weeks before admission. There was no history of spurious labour pains. The sutures of the softened fetal head could be easily felt through the thin abdominal wall, and the state of affairs was readily

diagnosed. The sac, which was largely extra-peritoneal, was removed entire, with the body of the uterus, to which it was intimately united. The left appendages were normal. The right could not be found, either at the operation, or on later examination of the specimen. The right round ligament ran into the sac. The placenta, greatly thickened by blood clot, was attached to the back of the uterus and to the tissues at the base of the broad ligament.

Mr. Barber also showed a uterus with a right *tuberculous pyosalpinx* and a left tuberculous tubo-ovarian swelling. A nodule of caseating material enlarged the right angle of the uterus, around the intestinal part of the tube. The parietal and visceral peritoneum was studded with tubercles.

Sir William Sinclair showed long *sea-tangle tents* suitable for the induction of labour. The tents were six or seven inches in length. Similar ones had already been used, with good results in several cases.

## LIVERPOOL MEDICAL INSTITUTION.

## PATHOLOGICAL AND MICROSCOPICAL SECTION.

MEETING HELD THURSDAY, NOVEMBER 11TH, 1909.

Mr. T. H. BICKERTON in the Chair.

THE following specimens were shown:—

Epithelial odontome; exophthalmic goitre; three epitheliomata from one lip, by Mr. Thelwall Thomas and Mr. Mackarell.

Melanotic sarcoma of the eye, two cases; pseudoglioma of the eye, by Dr. Stevenson and Dr. Harcourt.

Melanotic sarcoma; glioma of retina, by Mr. Charles G. Lee and Dr. Harcourt.

Hour-glass contraction of the stomach, by Dr. Gordon Gullan.

Skull and brain, pneumococcal meningitis, by Mr. R. E. Kelly and Mr. Mackarell.

Phagocytosis of pneumococcus in cerebro-spinal fluid, by Dr. Ernest Glynn.

Naso-pharyngeal fibroma; tracheal tuberculosis, by Mr. Thomas Guthrie.

Malignant streptococcal endocarditis; primary carcinoma of adrenals; congenital cystic kidneys from a man, æt. 44, and tubercular appendix, by Dr. Nathan Raw.

Thoracic aneurysm with rupture into superior vena cava, by Dr. Lloyd Roberts.

The specimens were discussed by Drs. Bradshaw, Marsh, Murray, Bligh, Hay, E. E. Glynn, J. H. Abram, and Harcourt.

Dr. R. J. M. BUCHANAN read a short paper on  
OBSERVATIONS ON CYTOLOGICAL METHODS.

He held that in the body as a whole somatic or systemic death took place: the same term is applicable to the death of the cell as a whole, and that systemic cell death takes place prior to disintegration. Recognising the occurrence of death of the individual in instantaneous rigor or cadaveric spasm, he held that cells could die in instantaneous rigor, that this condition is produced and preserved permanently by the most approved methods of instantaneously fixing tissues during life, and that by this means cells could be fixed in any phase of their existence, and the appearances coincident with their latest activities permanently recorded. He drew distinctions between cells which were allowed to die slowly prior to examination of cells *in vitro*, being regarded as equivalent to examination *in vivo*, and pointed out the danger of the tendency to regard these terms as synonymous in experimental methods.

The paper was discussed by Drs. G. C. E. Simpson, Harcourt, E. E. Glynn, and J. Hill Abram and Dr. Buchanan replied.

The paper was illustrated by microscopic specimens showing cells fixed and preserved in instantaneous rigor.

## CENTRAL MIDWIVES BOARD.

MEETING HELD NOVEMBER 25TH, 1909.

Dr. CHAMPNEYS in the Chair.

## THE RIGHT OF PRACTITIONERS TO DISMISS MIDWIVES.

THE case of a midwife who had been dismissed from a case by the medical man, whom she had called in on account of the condition of the baby's eyes, was dealt with at some length. A letter had been received from the M.O.H. for Bolton, asking for advice in the matter. The facts, as stated, were that the midwife, soon after effecting delivery, noticed that the child's eyes were inflamed, and summoned a doctor. He pronounced the case to be one of ophthalmia, and told the midwife to cease her attendance altogether. There appeared to be nothing abnormal in the mother's condition. The questions arose whether the midwife ought to have obeyed his instructions (as she did), when the rules of the C.M.B. make her responsible for the care of the mother for 10 days, and whether any doctor, other than the local supervising authority, has any right to dismiss, or in other words, suspend a midwife from her duties. There was a division of opinion, some offering a distinct negative to these questions, but the Standing Committee had drafted a reply to the following effect:—

(a) That it would not have been right for the midwife to have disobeyed the instruction of the medical man, and to have kept on with the case until she had received notice from the Local Supervising Authority.

(b) That the medical man being responsible for the case, his orders, however ill-considered, must be obeyed. (Rule E. 6.)

(c) That as regards the question of suspension of the midwife to avoid spreading infection, this was not necessary.

Sir GEORGE FORDHAM suggested that the Board was not called upon to give advice upon such matters, upon which the question was asked. After further discussion, a resolution was passed by the majority to the effect that the letter should be acknowledged without any advice.

Several letters had been received with reference to the admission to the Roll of women who had failed to enrol themselves under Section 2 at the proper time. This had already been done, under special circumstances once or twice, and the principle is embodied in one of the recommendations of the Select Committee; but Sir George Fordham objected that the Board had no legal right to do so. Accordingly a resolution was passed that the Privy Council be requested to sanction an alteration in the rules, enabling the Board to enrol women who, through no fault of their own, had failed to enrol themselves before April 21, 1905.

## THE ADMINISTRATION OF DRUGS BY MIDWIVES.

Miss Bernard-Boyce, the Inspector of Midwives for Norfolk, had written, asking for information as to the extent of the right of a midwife to administer drugs. It was agreed—

That a reply be sent embodying the principles laid down in a circular letter to the examiners, dated June 8th, 1907, on the subject of the administration of drugs by midwives.

This letter states that a midwife is not to be discouraged by the examiners from giving certain drugs which she has been taught to use in her training-school, provided she satisfies the examiners by her knowledge of them. Mr. GOLDING-BIRD appeared surprised that midwives should be allowed to "prescribe," as he expressed it, but the Chairman pointed out that certain drugs were essential in the practice of midwifery, and it was impossible to allow a woman to die because the midwife was not to give ergot, for example. Miss PAGET wished to accentuate the distinction between a midwife and a nurse, the former being qualified to act in cases of normal labour without a doctor.

Approval as a training school was granted to the following hospitals:—Cama Hospital and Allbless Hospitals, Bombay, Civil Hospital and Victoria Hospital for Women and Children, Hong-Kong, Home

for Mothers and Babies, Woolwich (subject to a satisfactory report from the local supervising authority).

Dr. Atkinson's motion:

That it be referred to the Standing Committee to consider and report as to any administrative methods which it may be desirable to vary in the light of the report of the Midwives Act Committee, was carried, also a resolution put forward by

Mr. Parker Young:

That one member of the Central Midwives Board be elected as a direct representative by the registered medical practitioners in England and Wales, in the same manner and at the same time as the direct representatives on the General Medical Council are elected.

A letter had been received from the Hon. Secretary of the Chelsea Division of the Metropolitan Counties Branch of the British Medical Association, enclosing a copy of a resolution passed at a meeting of the medical practitioners of Chelsea and Fulham, refusing to attend women in, or immediately after childbirth, or in respect of puerperal maladies, in response to emergency calls from midwives, unless the Boards of Guardians of Chelsea and Fulham guarantee to pay the fee. The Board agreed to forward this communication to the Privy Council.

The next general meeting will be held on December 16th.

## CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS  
ABROAD.

## FRANCE.

Paris, Nov. 28th, 1909.

## VULVO-VAGINITIS IN CHILDREN.

VULVO-VAGINITIS is a frequent affection in children. The infection is localised first in the vulva and subsequently extends to the vagina. The labia are inflamed and the mucous membrane covered with mucopurulent secretion of yellowish colour, and frequently very abundant. Where vaginitis exists at the same time, the matter exuded through the perforation of the hymen.

Examined through the microscope, the flora presents, besides polynuclear leucocytes and epithelial cells, ordinary pyogenic microbes, staphylococci, and, in a number of cases, gonococci, especially where the pus has a phlegmonous aspect.

The one cause of vulvo-vaginitis, says Dr. Marfan, is contagion. Transmission is generally effected by cohabitation in the same bed with a person, mother or sister, affected with leucorrhœa. The secretions staining the sheets come in contact with the vulva; certain toilet articles, as towels, sponges, etc., might also be incriminated. Contagion may also take place in schools by water-closets, and, above all, by onanism.

The influence of rape has been very much exaggerated, and prudence should be observed in giving an opinion on the possibility of criminal contamination.

The complications of vulvo-vaginitis in children are more or less those of adult women, but the gravest and the most frequent is that of peritonitis due to gonococci. It sets in suddenly with rigor, fever, extreme pain in the abdomen, vomiting of greenish matter, and griped face. The abdomen is swollen and sensitive to pressure, especially in the hypogastric region. The pathognomonic sign of this form of peritonitis is intense cyanosis of the extremities; the cheeks, ears, nose, hands and feet are violet and cold. However, all those alarming symptoms, which would seem to forebode a speedy fatal termination, disappear gradually in ten or twelve days; consequently, no surgical intervention should be thought of. Among other complications may be mentioned purulent ophthalmia, acute rheumatism, and endocarditis.

Several varieties of vulvo-vaginitis may be observed: vulvitis due to saprophytes and met in ill-cared and

ill-nourished children, pyodermic vulvitis (impetigo, aphthæ), pseudo-membranous vulvitis provoked by diphtheria and eczema of older girls (difficult to cure).

The treatment of vulvo-vaginitis is tedious and difficult. The parts should be frequently bathed with a solution of permanganate of potash (1-500). A soft Nélaton catheter of fine calibre is introduced into the vagina through the foramen of the hymen and adjusted to the douche; the liquid should flow with gentle pressure so as to guard against distension of the vagina. The child should be kept in bed for three or four days, as walking increases the secretion. After each injection a piece of antiseptic gauze should be placed between the labii.

In chronic cases the parts might be touched with a solution of nitrate of silver (1-100), while general treatment, tonics, cod-liver oil, etc., should not be neglected.

#### PYRAMIDON IN ODONTALGIA.

By reason of its anti-neuralgic properties and its perfect tolerance, pyramidon is an excellent remedy for all forms of odontalgia. In continued and excruciating pain, 10 grains three times a day give great relief. To calm the pain after extraction of a tooth, a wafer of 10 grains taken ten minutes before the operation is very successful. In periostitis one or two wafers give also relief, the last to be taken at bedtime. Neuralgia of the trigeminus yields also readily to salicylate of pyramidon.

#### PEDICULI OF THE HEAD.

Petroleum, 4 oz.  
Peru balsam, 1 oz.  
Olive oil, 2 oz.

#### SCABIES.

Proof spirit, 1 dr.  
Peru balsam, 4 dr.  
Benzoic acid, 15 gr.  
Oil of cloves, 1 m.  
Vaseline, 4 oz.

#### ECZEMA.

Sulphur, 15 gr.  
Salicylic acid, 15 gr.  
Camphor, 15 gr.  
Cade oil, 2 dr.  
Oxide of zinc, 4 dr.  
Vaseline, 1 oz.

#### GENERAL PARALYSIS.

General paralysis, or softening of the brain, is an affection usually considered refractory to treatment. However, it would seem that, with nucleinate of soda, given in large doses, great improvement, and sometimes a complete cure, can be obtained. Two drachms and a-half of a ten per cent. solution are injected every three or four days subcutaneously. The local reaction, however, is sometimes very great, the temperature rising to 104°, and abscesses may result which require incision, but frequently they yield to application of cold compresses.

Out of 21 patients treated by these injections by Prof. Donath, 10 were sufficiently cured to return to their work, 5 were considerably improved, while 6 experienced no benefit.

#### GERMANY.

Berlin, Nov. 28th, 1909.

At the Medizinische Gesellschaft, Hr. H. Neumann spoke on

#### PREGNANCY AND GLYCOSURIA: THEIR MUTUAL RELATIONS AND TREATMENT.

He said it was already recognised on many sides that diabetes and pregnancy were not often met together. Naturally, he had only the excretion of grape sugar in mind in discussing the subject, as milk sugar and pentose were excreted during pregnancy.

The excretion of grape sugar might be either a pure alimentary glycosuria, or it might be a true diabetes; even this demanded a lengthy period of observation. Independent of the difficulty there was in pregnancy taking place in diabetes, the combination of the two was the more rarely observed, as the woman who was pregnant was inclined to attribute her troubles to the pregnancy, and to say nothing about them. That class

also had to be separated in which the diabetes was present before the pregnancy began from that in which it came on first during the pregnancy.

Whilst fewer women were diabetic than men, the mortality was greater amongst females, the majority of them dying between the ages of 30 and 40—i.e., during the period of sexual activity. In spite of this, the danger of coma, as well as of tuberculosis, the chief dangers in diabetes, was not increased by the pregnancy.

In the speaker's opinion the induction of premature labour was not indicated; the interruption of the pregnancy had no influence on the diabetes. On the other hand, any operation on a diabetic patient was a danger when associated with excitement, and was at most permissible in cases of repeated pregnancies that were the cause of distress to the patient. He had observed 6 cases of gravidity with diabetes; the labour ran a favourable course in each; neither during the pregnancy, nor the labour, nor during childbed, were there any untoward disturbances.

He took the comprehensive standpoint that diabetic maidens should not marry, that married ones should not conceive. Should a diabetic woman, however, become pregnant, the pregnancy should not be interrupted, but the patient should be watched carefully, and subjected to a rational diet.

Hr. Kraus bore tribute to the correctness of the views expressed, and asked whether the infrequency of pregnancy in diabetes was due to disturbed tissue change or to some complication such as endometritis, which was by no means infrequent in that disease.

Hr. Gottschalk was of opinion that the disturbances in the sexual apparatus of diabetic females were due entirely to disturbance of tissue change, as was shown by the frequent amenorrhœa, as well as by the more rare hæmorrhage, that accompanied it. Interruption of the pregnancy was not necessary in diabetes; regulation of the diet was generally sufficient.

Hr. Leopold Landau believed that diabetic women were so rarely pregnant because they had amenorrhœa from disturbance of tissue change in the ovary. The danger of diabetes in gravidity was not very great when the diet was rational.

Hr. Hirschfeld was of opinion that gravidity was a grave complication of diabetes, but he would not advise interruption of the pregnancy. He pointed out that the excretion of sugar frequently improved after the climacteric.

Hr. H. Elsner showed a new gastroscope modified from the idea of the cystoscope. For the purpose of passing the flexure of the œsophagus readily it was provided with an indiarubber tip. He also showed a number of drawings of the interior of the normal stomach taken from life.

Hr. Klemperer said that the stiff tube was dangerous and exceedingly disagreeable to the patient. Gastroscopy would not be of any practical importance until a usable instrument made of flexible material was brought out.

At the Verein für Innere Medizin und Kinderkrankheiten, a discussion took place on an address by Hr. Immelmann on

#### THE PRESENT POSITION OF THE RÖNTGEN EXAMINATION OF THE URINARY APPARATUS AND CONCRETIONS.

He said the difficulties of bringing the urinary apparatus on to the plate were extremely great, but in the cases of urinary concretions they were not so great.

Hr. Zodek said that from the illustrations shown by Immelmann it was evident that diagnosis had become more refined. Whether the shadows were cast by stones could sometimes be determined by a comparison of the forms of these shadows with concretions.

Hr. Roth said the question frequently came up whether certain symptoms were caused by nephritis or calculi, and here a Röntgen examination was a great help. In Caspar's Klinik very few Röntgenographic deceptions had taken place.

Hr. Klemperer appeared to summarise the opinions of speakers when he gave a report of his own experiences during the past two years. On 7 occasions when the plate was negative he had removed calculi; three

times the plate showed a stone when none was found at the operation. He now required that two plates should be taken, and that the shadow must show in the same place in each; but even with this precaution there had been an error of diagnosis in one case. One must, therefore, maintain an attitude of reserve in regard to Röntgen pictures.

### AUSTRIA.

*Vienna, Nov. 28th, 1909.*

#### FUNCTIONAL DISTURBANCE IN THE PYRAMIDAL REGION.

At the Gesellschaft der Aerzte, Strümpell presented a child with an abnormal sense of feeling on the left side of the face, which was followed by Jacksonian epilepsy. This commenced in the lower part of the face, and extended rapidly over the left side, affecting first the arm and then the leg, followed by severe headache and vomiting. The papillæ at the fundi of the eyes were greatly congested, and seemed to depend upon some tubercular centre. The patient suddenly became febrile, with a catarrhal condition in the apex of the left lung. Closer examination showed that the grosser sensations could not be recognised, such as pain, temperature, and touch. On the other hand, the feeling of dryness or weight appeared as a heavy, deep pressure; when the finger was drawn heavily across the skin it seemed to the patient as an isolated movement. It was thus evident that the function of the pyramidal paths which convey the finer movements and sensations were unaffected, while the others, more rough and exposed, were disturbed.

#### MEASUREMENT OF BLOOD PRESSURE.

Winternitz said that the measurement of the blood hitherto was recognised under two different methods, viz., pressure in the blood vessel and resistance of the vascular wall, which can scarcely be separated one from the other. When the vascular wall is greatly thickened we find that the apparatus registers a higher blood pressure than another vessel under the same circumstances with a thinner wall. This experiment can be easily performed with two india-rubber tubes whose calibres are the same, and the water pressure equal in both. It will be observed at the outlet that it requires a greater force to check the thick wall tube than it does to stop the thinner wall tube. Federn retorted that arteries were not comparable to india-rubber tubes, as a thick-wall artery often gave a lower pressure than did a thin-walled vessel in similar circumstances. Exner said that Basch had proved in a normal radial artery that the external pressure was three m.m. of mercury higher than the internal pressure, even when the vessel was almost closed by compression. Stejskal remarked that the experiments of Basch were even higher than that, as he records a case where a rigid carotid had an external pressure of 8 m.m. more than the internal to close the lumen. Winternitz replied that his remarks were confined entirely to clinical results, and he was led to the conclusion by his observation in men with high blood pressure, who have no cardiac hypertrophy, although this condition may exist for years.

#### WASHING OUT MIDDLE EAR.

Urbantschitsch read a short article on the treatment of the middle ear when suffering from chronic otitis. After the ear has discharged for a long time, it is difficult to clear the middle ear out without washing through the eustachian tube from the pharynx, as the tube itself is usually more or less involved in the inflammation. He, therefore, recommends a thorough washing of the nasal cavity and tube, after which he inserts into the eustachian tube a celluloid bougie well smeared with an astringent. He considers this form of treatment also suitable for perforation of the tympanum.

#### HORSE-SHOE KIDNEY.

Paschkis next presented three cases of this disease, one of whom was 57 years of age, who had complained for ten years of a burning pain on passing water, which was associated with strangury, and he never was able to retain urine more than two hours, by day or by night, the fluid being always very muddy. A few weeks before admission to hospital he was attacked

every 24 hours in the right renal area. An examination gave very little information, the part being somewhat sensitive to pressure, while the lower pole of the kidney could be easily felt. The urine was cloudy, containing pus and bacteria, while the cystoscope revealed chronic cystitis, and the ureters in their normal position. The Röntgen rays revealed a small stone about the size of a hazel nut in the right kidney. With regard to the ureters the right contained pus and diluted urine, while the secretion from the left was free from pus and contained normally concentrated urine. The indigo carmine test was delayed in the right kidney, with a very feeble reaction.

It was decided to operate, with the following result: The upper pole of the kidney was easily removed, in it could be felt the stone; the lower pole lay embedded in cellular tissue across the spinal column towards the left side, forming a horse-shoe. The right half of the kidney was somewhat friable and bled profusely on removing the stone, while around the pelvis of the organ the vessels were greatly dilated.

About two months after the operation another stone was removed from the funnel-shaped wound, though nothing could be seen or felt during operation. Since then the patient has recovered health, the urine is healthy, and he is now considered perfectly well.

### HUNGARY.

*Budapest, Nov. 27th, 1909.*

#### THE SUBCUTANEOUS EXTIRPATION OF CERVICAL GLANDS.

OWING to defective hygienic conditions, there are too many cases of cervical glands to be found in Hungary. In fact, if we look at the statistics of the surgical operations done in a provincial general hospital, we at once confirm our statement by the striking large number of operations performed on account of cervical glands. As most of the cases occur in women, owing to their less out-door occupation, the resulting scars, which disfigure the neck, were ever the subject of investigation, how they could be removed, and as the removal itself leaves some, though a thread-like, scar, our surgeons had to look after some more efficient procedure of dispensing with the disfiguring scars. Dr. Dollinger, Professor of Surgery at the University of Budapest, has finally found an effective method of extirpating the glands without leaving a visible scar on the neck. Nominally, he makes an incision close to the anterior end of the hairy scalp, sufficient to put in two fingers to separate the skin of the nuch until he reaches the glands to be removed. With a little practice, these glands can be severed from their base without the aid of a knife or a scissor, simply by means of adequate manipulation of the fingers. After the removal of all the glands, the pouch is irrigated with a weak solution of corrosive mercury, and the incision wound closed by stitches, leaving in drain tubes at both ends of the wound. The operation can be performed only in cases where the glands are not yet suppurating. If the separation of the glands is difficult, or it endangers the tearing of a gland, then Dollinger uses an elevator invented by himself for this purpose. In most cases he is able to remove all the glands without seeing the field of the operation. The finger-tips feel even the smallest glands with a little practice. However, in cases where small glands are felt in great number, then it is advisable to reflect light into the pouch between the skin and the neck. This cannot be done in every case, particularly where the skin is rigid, and not loose.

The manipulation does not bruise the tissues, and there is no danger of tearing veins or arteries. Of course, great care must be taken to save them from violence. Dr. Dollinger has such a great practice in performing such operations, that he is able to perform them in 15-20 minutes, even where there are as many glands as in a potato field.

He warns his followers on these points:—

(1) If those glands are infiltrated which surround the accessory nerve under the upper end of the sternocleidomastoid muscle, then the nerve must be carefully separated. This being near to the site of the

incision, the field of operation can be seen, and the fingers controlled by the eyes.

(2) If there are infiltrated glands within the pouch of the sub-maxillary gland, then this pouch must be cut prior to the digging out of the infiltrated glands. Care must be taken not to injure the facial vein.

(3) The hæmorrhage is of no importance in most cases. If, however, there is considerable bleeding, then the best thing is to plug the pouch, and continue the operation next day.

Dollinger performed this operation in 200 cases, out of which 167 healed by primary intention, in 33 cases suppuration ensued for a short time.

On the day following the operation most of the patients suffered from an acute tonsillitis, probably as the result of the traumatic influence of the manipulation. However, this is of no importance, and the symptoms connected with it generally subside in two or three days.

### WINTER VOYAGES FOR HEALTH.

[FROM AN OCCASIONAL CORRESPONDENT.]

THE popular notion of taking the annual holiday when "the sun shines on both sides of the hedge" has, like everything in this mundane existence, its drawbacks. When the holiday is past, we have all the worst of the weather of our fickle climate in front of us, whereas by deferring it to the winter we can break through the monotony of fog and cold, and escape by sea without great expense to sunshine and warmth. There are, doubtless, many of your readers like myself, to whom absence from home is not always convenient in summer, and having once taken my outing in winter by accident, I now invariably do so from choice. The route I followed on the present occasion (November 2nd to November 22nd) would appear not to be well known to English travellers, and with your permission I will give a few notes for their information, after a voyage which has afforded me healthy recreation at quite a modest outlay. Let my readers bear in mind, if bad sailors, that a sea voyage is not necessarily all sea, that by this route (the Nederland line, whose ships sail fortnightly from Southampton) they can land for a few hours every second day and gain knowledge of other countries, which would be unendurable during the summer months. Nor need they fear the weather, as after the equinoctial gales of October, one can generally count on the dictum that "After a storm comes a calm," and having taken a dozen voyages during November, December, and January, my experience goes to prove the rule, the present being no exception. The first thing that arrests one's attention on the Nederland ships is the troop of Javanese attendants, with their turbaned heads and sandalled feet. Java having been ceded to Holland by Great Britain at the beginning of the last century, the Dutch make good use of their colonial subjects, in the same way that we find our Indian subjects on board the Peninsular and Oriental line. These little men, whose stature is about that of the Japanese, have very pleasing faces, wait upon your every possible comfort, both in the cabin and at table, move about as noiselessly and as swiftly as cats, seeming to delight in doing duties obviously agreeable to them.

Our first port of call was Lisbon, but the capital of Portugal can by no stretch of imagination be pronounced attractive. It has one magnificent avenue in the residential quarter, where the date-palms and semi-tropical shrubs luxuriate, but elsewhere, as with most large seaports, everybody seemed on the rush, and the shipping interests reigned supreme. Our next stopping place, Tangier, was of a totally different character, interesting beyond expression, dirty beyond description. What a seething population was here, every nationality under the sun seemed to jostle you everywhere along its narrow thoroughfares, and as the native part of the city is built on the slopes of the mountain-side, donkeys do the duties of vehicles, for visitors with or without impedimenta, Arabs in their quaint costumes, and Nubians with not too much of the latter, are here

"moved on" in this primitive, happy-go-lucky method of a semi-civilised and ancient people. In the seething crowd were snake-charmers, Kabyles, with their numerous wives, whose eyes only were visible to the common horde, itinerant vendors of every conceivable commodity, and donkeys innumerable. On the shore were encamped hundreds of Moors who, on our return a few days later, had struck their tents and gone to the war. We saw a scuffle between a wiry Arab and a fat little Spanish gendarme; the latter was getting the worst of the argument, and we thought it wiser not to stay. Doubtless, much of the excitement prevalent when we were there was owing to the proximity of Tangier to the seat of war, yet in spite of its nastiness from a sanitary point of view, we left with the most pleasurable reminiscences of the buoyancy and spirit of its people. From here we steamed on to Algiers, through Gibraltar and the Mediterranean, but as I have previously described this cosmopolitan centre in your columns, and it is better known to English folk than Tangier, I need not further allude to it. It was a delightful run from Algiers past the Atlas range on to Genoa, in which latter city we stayed four days, awaiting the return steamer.

Genoa, which although not a city to tempt one for the sake of pleasure, is one nevertheless of great historical and architectural interest. Abutting on the main thoroughfares stand the magnificent palaces of the nobles and the doges, who governed and warred against neighbouring States, until the proud Genoese were finally subdued by the Venetians. These relics of a mighty past are still in perfect preservation, and give additional zest to the imagination when recalling the history of bygone ages. Genoa is also a convenient centre from which to take excursions to the magnificent mountain and coast scenery of Portofino, the health resorts of Rapallo, Nervi, and other spots on the Levantine Riviera now coming to the front.

Our return boat was the *Vondel*, a new and very fine ship of the Nederland Company, whose boats are officered by a most courteous set of men, who, although of Dutch nationality speak excellent English, and do everything possible to make the voyage agreeable. The food also is varied and ample, and the cost of the voyage exceedingly moderate. When I mention that the twenty days' voyage out and home cost but £16 10s. for first saloon, inclusive of everything except wine, it will, I think, be considered a luxury of sea voyages in search of health at a minimum expense.

### FROM OUR SPECIAL CORRESPONDENTS AT HOME.

#### BELFAST.

A QUESTION OF FEE.—An interesting case came up in the Recorder's Court last week, when Dr. W. H. Ferran sued the Belfast Corporation to recover 10s. 6d., a fee for professional services to a child who had been injured by a Corporation tram-car. It appeared that the child was knocked down by a car, and carried to the nearest doctor's house by a civilian, accompanied by the tram conductor. Dr. Ferran attended to the case and dismissed it, and shortly afterwards a tram inspector called to inquire as to the nature of the child's injury. The man who carried the child stated that he had picked it up, and at the suggestion of the conductor carried it to the doctor's. For the defence it was said that what was done as a voluntary and humane action was here sought to be turned into a matter of £ s. d. It was estimated that there were about twenty-five tram accidents every day in the city, and if doctors were to be paid for first aid in every case, it would mean thousands a year. Fees had been paid before, but in those cases the injuries were serious, and the doctors had been put to special trouble and pains. His Honour said that the child was knocked down by a tram-car belonging to the Corporation, and by the direction of their servants the child was taken to the doctor. He held the Corporation liable, and he gave a decree for the amount

claimed. Undoubtedly the profession in Belfast owes a debt of gratitude to Dr. Ferran for fighting this case, for here, as elsewhere, the public is only too ready to be "humane" at the expense of the doctor.

**THE WOMEN STUDENTS OF QUEEN'S UNIVERSITY.**—The first of the geographical changes brought about by the establishment of the new University took place last week, when the women students moved into what was lately the Registrar's house, on the south side of the College, deserting the stuffy little rooms which till now have been sacred to their use. The old rooms did well enough for the dozen or so of women who attended classes in the early days of their admission, but now there are over a hundred women attending, and suitable rooms are a necessity. The students gave an "at home" on taking possession of the new rooms. These are large and airy, and will afford ample accommodation for meetings of clubs and societies, as well as ordinary reading and luncheon rooms. The Vice-Chancellor, in speaking at the opening, said it was interesting to recall the fact that these rooms had for many years been the home of the great Professor Andrews, who was a strong opponent of the movement for the admission of women students.

**DONEGAL COUNTY COUNCIL SCHOLARSHIPS.**—The Donegal County Council have decided to give six scholarships each year, of the value of £45 per annum for three years, four to be given to students going to the National University, with an Irish language test, and two to students going to Dublin University or Magee College, Londonderry, or any other University the student may select. It was at first proposed that the two last-named scholarships should be given to students attending the Queen's University of Belfast, but not unnaturally this was objected to by the friends of Magee College, whose influence is strong in Donegal, as Derry is practically the business centre for that county.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### A MEMBERSHIP DIPLOMA FOR ALL THE ROYAL COLLEGES OF SURGEONS.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR*

SIR,—With heartfelt gratitude, I re-echo the question of "An Old R.C.S.I. Student" in your issue of November 24th last:—Why should there not be a membership of the Royal College of Surgeons of Ireland? Why, for that matter, should there be licentiates and fellows of the College in Scotland and of Ireland, and members and fellows of the Royal College of Surgeons of England? What is the reason for this senseless multiplication of qualifications that has been going on since bluff King Hal set the ball a-rolling by founding the Royal College of Physicians of London? The insensate and selfish rivalry of the competing schools has ended in a very Babel. The community asks for a qualified medical man, and the rival Boards give him a selection of a score and upwards, designated by grotesque and variegated titles and high-sounding names. The public will be content with a one-portal qualification for medicine, as there is a single one for law. It is only close corporations that hug the many portals to the undoing of their diplomates and of future generations of students. By all means let us adopt Mr. A. T. Norton's excellent suggestion and begin the simplifying process by amalgamating all the diploma-granting bodies of the United Kingdom with a State University degree of Medicine. Surely a profession so humane and intellectual as that of medicine should hail the prospects of equal opportunity with enthusiasm. Why should the diplomates give quarter to the corporations which have taken their money and have given no vestige of participation in the affairs of the Colleges to the lower ranks of their alumni? The Edinburgh College of Surgeons have repeatedly declined to take any steps towards instituting a membership diploma for the benefit of their

licentiates. It is a pity the Scotch and Irish licentiates cannot join in presenting a strong united protest to the Government, asking for inquiry into the present chaotic system of medical qualification, with special reference to their own Colleges, with the non-representative control, and their non-elective representation on the General Medical Council. Meanwhile, the Colleges will be wise in adopting a conciliatory attitude as regards the grievances of their diplomates.

I am, Sir, yours truly,

A MERE LICENTIATE.

### SUPPURATION IN THE ACCESSORY NASAL SINUSES.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—Owing to what is obviously a misprint of "majority" for "minority" in the quotation from my lecture in my reply to "A Dental Surgeon," there is an apparent contradiction between it and the view expressed lower down.

The view I have endeavoured to express is, that it is only in a large *minority* of the cases that dental caries, etc., can be shown to be a direct cause of maxillary suppuration.

I am, Sir, yours truly,

JAMES DONELAN.

Manchester Square, W.,  
November 17th, 1909.

### "THE DEADLY LEAVEN OF VENEREAL DISEASE."

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—Permit me to draw attention to a passage in your notes this week which must, I think, have been written under a misapprehension. You speak of a salutary British law, intended to check venereal disease, being abolished by a weak Government, "with the result that venereal disease has since been unrestrainedly at work among all classes." I believe this statement is not borne out by the facts. On the contrary, there has been for the past 24 years an almost unbroken yearly diminution of venereal disease.

It is true that when the operation of the Contagious Diseases Acts was first suspended in England the statistics of disease in the Army—practically the only, or almost the only, reliable statistics as to these diseases—did go up. This went on for two or three years, each year being—though in diminishing ratio—worse than the last. Apparently it is this fact which has been persistently quoted ever since, as a proof that it was a blunder to do away with the Acts, no account being taken of anything that has happened since. But what did happen? In spite of this increase of disease, the Acts were not put in operation again, but were, in 1886, finally rescinded, and from that very year there has been a steady, continuous diminution of venereal disease in the British Army. The official figures are as follows, the increase in 1901-1903 being accounted for by the South African War. The figures represent admissions to hospital for venereal diseases per thousand of the troops. In 1885 the figure had reached 275 per thousand. Then follows:—1886, 267; 1887, 252; 1888, 224; 1889, 212; 1890, 212; 1891, 197; 1892, 201; 1893, 195; 1894, 182; 1895, 174; 1896, 158; 1897, 140; 1898, 133; 1899, 122; 1900, 93; 1901, 105; 1902, 123; 1903, 125; 1904, 108; 1905, 91; 1906, 82; 1907, 72.

Other statistics, official and unofficial, seem, as far as they go, to indicate the same thing—a real reduction of disease of this kind in our population, civil and military.

Things are bad enough still, but it is not desirable that we should make them out worse than they are.

I certainly am not one of those, if there are any such, who would have these diseases kept going as a scourge for either the guilty or the innocent. I think we need to use every available means of prevention and cure. But I think it is hardly realised even yet to what an extent everything depends on the goodwill of the individual. At a time when the Contagious Diseases Acts were in full blast in India, the young soldier was told in the barrack-room that he was "not a soldier" till he had "had his three doses of disease," and he promptly went and got it, spite of

all official arrangements for his doing otherwise. Nowadays the Army authorities are awake to this; they are enlightening the men and getting gradually a better tone in relation to this matter. Improvement may be slow, but it is real and vital progress, and, as an Army Medical officer said the other day, in a lecture before the Eugenics Society, "Our Army is the only one that shows an improvement in this respect."

So let us work on, not as those who are without hope. Doctors have an immense influence in their hands if they will only use it. But as to the system embodied in the Contagious Diseases Acts, I say what I know when I say that in those countries where it still exists it is the despair of its very adherents.

I am, Sir, yours truly,  
B. LEPPINGTON,

Member of the International Society for the  
Prophylaxis of Venereal Diseases.

November 20th, 1909.

#### QUACK "TONICS" CONTAINING ALCOHOL. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The enormous increase in the use of quack medicines in late years has made it necessary, in a large proportion of cases, to inquire in what way the patient has been dosing himself before presenting himself for treatment. This inquiry sometimes needs tact. Many persons are averse to confessing their faith in quackery, and parents especially are often ashamed to admit that they have added to their children's sufferings or imperilled their lives by "home" treatment with advertised nostrums. Very often, during treatment by their medical adviser, patients go on using some pernicious compound which is itself either giving rise to or aggravating the symptoms for which relief is sought. This is especially the case with the largely advertised "tonics," the sole potent ingredient of which is alcohol. I have lately seen a typical case. I think it is worth the briefest possible description, if only for the sake of junior practitioners. I confess that the patient had been to a young practitioner in this neighbourhood before coming to me, and I was not able to defend him when my patient expressed his discontent that the questions I put had not been suggested by my neighbour. The patient was a dark, "bilious," middle-aged merchant of sedentary habits. He complained of being run down, and depressed sometimes almost to the point of suicide. He thought he needed tonics and stimulants, and, in addition to two or three whiskies and sodas during the day, with a superabundance of solid food, he had for some weeks been taking during each day three glasses of the most widely advertised alcoholic quack "tonic." His symptoms, including habitual constipation and a tendency to piles, were exactly what one would expect from such a *régime*, and all the symptoms vanished rapidly under simple treatment. The clearing out of his loaded bowels, and their regulation, together with a suitable dietary, have put this patient at once into the enjoyment of perfect health. How many thousands of people are going about leading miserable lives, and with their value as citizens diminished, owing to the fraudulent traffic which you so strenuously attack?

There are some evident reasons why I should prefer to conceal my name, and I beg to be allowed to subscribe myself,

Yours truly,

A SENIOR PRACTITIONER.

Liverpool, November 16th, 1909.

### OBITUARY.

THOMAS SECCOMBE, R.N., M.D. ABERD.,  
F.R.C.S. ENG.

WE regret to announce the death of Dr. Thomas Seccombe, one of the oldest surgeons on the retired list of the Royal Navy, who has died at Torquay at the age of 90.

Deceased was educated at the University of Edinburgh. He obtained the qualifications of M.R.C.S. of England in 1843, and the M.D. degree of Aberdeen University in 1865. He entered the Navy in 1845, and

was appointed Staff-Surgeon in 1853, Fleet-Surgeon in 1867, and Deputy Inspector-General of Hospitals and Fleets in 1880, when he retired from the Service. He served as a surgeon on the levies, and was present at nearly every engagement during the Kaffir War in 1851, for which he was awarded a medal. He was in charge of the field hospital at the taking of Rangoon, and took part in many boat expeditions in 1852, being mentioned in despatches and awarded a Burmese medal. In 1864 the Royal College of Surgeons elected him to the Fellowship in recognition of his professional attainments.

### MILITARY & NAVAL MEDICAL NOTES.

**INDIAN MEDICAL SERVICE—SUBORDINATE DEPARTMENT.**—It has been ruled that members of the Hospital Assistant Branch of the Indian Subordinate Medical Department are eligible for the Indian Distinguished Service Medal instituted by Royal Warrant, dated June 25th, 1907. The reason for the issue of such an order is not very clear, for surely it could not have been intended to exclude this deserving and useful class of native public servant from the grant of the medal. He is to be found in the field with medical establishments.

**LEAVE OF MEDICAL OFFICERS.**—It was about this Mr. Ashley interrogated the Secretary of State for War in the House on this subject. He asked whether Mr. Haldane would see that officers of the R.A.M.C. serving in Ireland shall this year receive the full leave to which they are entitled. The Secretary of State for War replied that under normal conditions it will now be possible to give every R.A.M.C. officer serving in Ireland throughout the year full leave, provided that he is willing to take it when the exigencies of the Service permit. Now, this has always been a great grievance, and naturally so—viz., that medical officers never seem able to get their full leave of 60 days. Many have found it very difficult to get even 30 days before embarkation for a foreign service tour. The verbally divisions and districts are under the complement of medical officers supposed to be allotted each, and it is thus the difficulty arises. But who is responsible for this chronic paucity? That is the question. Medical officers are, after all, human, and need the privileges enjoyed by other officers in the from work.

**"DETENTION BARRACKS."**—This is the euphemistic term for "military prisons," recently come into vogue. At the request of the Government of India, the Home authorities have agreed to depute Captain G. Haines, Commandant Detention Barracks, Aldershot, to visit India during this cold season (November to March) to inspect and report on the military prison and detention barrack system prevailing there.

**SOLDIERS' GRAVES.**—Most laudably, the men of the Royal Welsh Fusiliers are, by voluntary subscription, erecting new tombstones over and caring for the graves (where they can be located) of their comrades of the 1st Battalion who died in the last Burmese War in Upper Burma. In one little graveyard alone, Shwabo 40 of the regiment lie buried, while between there and Bhamo lie a number of others.

**SPANISH CASUALTIES IN MOROCCO.**—The Spanish authorities, according to a writer in the *Army and Navy Gazette* of November 20th, have lost in casualties about 3,000 and in sick some 7,000. He criticises unfavourably the administration in the field by stating that "leaves much to be desired." There are no regimental signallers, and the men, though of excellent material, are without training or discipline. The Generals, he says, are not good, and are indifferently backed up by the staff.

## REVIEWS OF BOOKS.

## MIDWIFERY FOR MIDWIVES. (a)

If a nurse wishes to consult a book which will give her a good idea of what a midwife should be, and how she should act, she can do no better than read the "Lectures to Practising Midwives" which Dr. Bennett has written. Each point is clearly defined, and the reader is informed exactly how to conduct her work in language which, though excellent, requires neither a classical scholar nor a public school education to understand. The Rules of the Central Midwives Board are given in full. Good advice is given through the book: "The rectal and vaginal douche apparatus must be kept quite separate"; "swabbing must always be done from before backwards," and other such maxims, which, though trivial, are important, appeal to us. The nurse is advised to conduct a routine examination in every case, and it is well explained how to diagnose abnormalities in order that medical aid may be summoned. The management of the puerperium is described accurately, but we should like to have seen more stress laid on the care which a nurse should take of herself when treating ophthalmia neonatorum. We may say that the personal hygiene for a nurse is excellently given in the commencement of the volume.

The illustrations are not new, but are good reproductions from the works of Jellett and Galabin.

We have no hesitation in strongly recommending the work to those for whom it is intended—namely, practising midwives.

## AURAL SURGERY. (b)

WHILE admitting the excellence of many larger treatises on aural surgery, we are not acquainted with a book which deals with aural operations in so concise and explicit a manner as this recent work by Drs. West and Scott.

The introduction places before the reader the authors' clinical observations on the rotation, caloric, and electrical tests for nystagmus in diseases of the labyrinth, a branch of otology which is yet in its infancy, but which the experience of the past three years has proved to be of fundamental importance in connection with diseases of the internal ear. The writers lay down specific rules for the guidance of the surgeon in deciding for or against operative interference in suppurative otitis media. All the steps of Schwartz's and the radical mastoid operation are minutely and accurately described in a manner which could not fail to be intelligible even to the uninitiated in aural surgery. Particular directions are given to enable the operator to avoid injuring such important structures as the facial nerve, lateral sinus, internal carotid artery, vestibule external semi-circular canal, and temporal lobe of the brain.

Great stress is very rightly laid on what we must consider as one of the primary principles of aural surgery—viz., the necessity for attacking all such complications of suppurative otitis media as labyrinthine suppuration, basal meningitis, sinus thrombosis, and brain abscess of otitic origin through the *fons et origo mali*—the middle ear.

Translabyrinthine combined with lumbar drainage is strongly advocated in the treatment of otitic basal meningitis, and promises to give far more happy results than have hitherto attended the inactivity of former otologists. The assistance which is afforded to the young specialist in the performance of aural operations by means of this excellent book is so complete that it might almost be termed a process of "spoon-feeding" for the embryo otologist.

The appended series of some fifty cases operated on

(a) "Lectures for Practising Midwives." By Victoria E. M. Bennett, M.B., B.S.Lond., &c. With Preface by Mrs. Mary Schallie, M.D., M.S.Lond. Pp. xiv. + 258. Illustrations 41. London: Baillière, Tindall and Cox. 1909. Price 4s. net.  
(b) "The Operation of Aural Surgery." By C. E. West, F.R.C.S., Aural Surgeon to St. Bartholomew's Hospital, and S. R. Scott, M.R., F.R.C.S., Assistant Aural Surgeon to St. Bartholomew's Hospital. Pp. xii and 201, with illustrations and plates. London: H. K. Lewis. Price 7s. 6d. net.

by the authors during the last five years serve as typical illustrations of the text, and form a practical recapitulation in synoptic form of the points in the diagnosis and treatment discussed in the earlier pages of the book.

## ELLIS'S BACTERIOLOGY. (a)

ALTHOUGH this book is evidently intended in the first instance for students of technical and agricultural bacteriology, still it is of sufficient medical interest to demand notice in our pages. After reading the book through carefully and critically, we can only come to one conclusion, namely, that the author not only knows his subject thoroughly, but at the same time is well able to impart his own knowledge to others. Few men have the gift of writing a really interesting book on bacteriology. Dr. Ellis has, and he displays his powers on almost every page. The scheme of the book follows the usual lines. It is the actual treatment of the subject-matter that is novel and refreshing. Bacteriology is not an easy subject to master, but no one can study this book without becoming possessed of a great number of facts which will lay the foundation for wider reading.

The sections dealing with the Nitrogen-Bacteria with Fermentation, and with the Industrial Applications of Fermentative Processes especially form very interesting and helpful reading. The book is well illustrated with over 130 figures in the text. It deserves to have a large sale, and we shall be surprised if a second edition is not very shortly called for. We cordially recommend it as one of the best introductions to the study of bacteriology with which we are acquainted.

## THE POCKET PRESCRIBER. (b)

"THE POCKET PRESCRIBER" is a convenient little book, which is intended to aid students in the art of prescribing. It contains 300 prescriptions, which are arranged alphabetically according to the diseases, over 200 in number, for which they are intended. The objection to this kind of work is obvious, and is well illustrated here by the fact that there is one prescription for enteric fever, and two for gonorrhœa. These may be quite unsuitable for the particular disease during most of its course. On the whole, however, the contents appeal to us on account of the simplicity of the prescriptions, and it will be more acceptable to students for that very reason. It costs one shilling.

## BILHARZIOSIS. (c)

DR. MADDEN is known as a writer of authority on the practical aspect of tropical diseases as seen in Egypt. In the present volume he sums up in brief space most of what is necessary to be known on bilharziosis, avoiding the discussion of controversial points, and approaching the subject from the standpoint of the practical surgeon. Nevertheless, he ignores neither the life-history of the parasite nor the pathological anatomy of the disease. The latter subject is excellently illustrated by photographs from specimens prepared by Professor Symmers, and from life in the author's wards.

Dr. Madden believes that infection by the parasite takes place through the skin, and he shows that 90 per cent. of the patients seen at Cairo come from the perennially irrigated Delta of the Nile. That is to say, the class most affected is that of agricultural labourers, whose work necessitates their standing barefoot in wet mud. The disease is rarely seen among women, except among those who work in the fields with the men. Almost every Egyptian of the agricultural class has been infected, but the disease is quite unknown in the upper classes.

(a) "Outlines of Bacteriology." By David Ellis, Ph.D., D.Sc.Lond., F.R.S.E., Lecturer in Bacteriology and Botany to the Glasgow and West Scotland Technical College, Glasgow. London: Longmans, Green and Co. 1909. 7s. 6d. net.  
(b) "The Pocket Prescriber." By James Burnet, M.A., M.D., M.R.C.P.E., Fellow of the Royal Society of Medicine; Lecturer on Practical Materia Medica and Pharmacy; Registrar to the Royal Hospital for Sick Children, and Physician to the Marshall Street Dispensary, Edinburgh. Edinburgh: John Currie. 1909.  
(c) "Bilharziosis." By F. C. Madden, M.D.Melb., F.R.C.S.Eng. Pp. 78. Illustrated. London: Cassell and Co., Ltd. 1907. Price 7s. 6d. net.

The pathological changes due to the bilharzia are somewhat various, but may be divided into two classes—the hypertrophic and the atrophic. In the former there is a marked proliferation of cells, chiefly the epithelial cells, leading to the formation of papillomatous growths. In the atrophic form the most notable feature is the formation of granulation tissue.

The affections of the urinary, intestinal, female genital, and cutaneous systems, are clearly described by Dr. Madden, while he also gives the appropriate surgical treatment in those cases where treatment is possible.

The book is pleasantly written, in straightforward, personal style, and is the most convenient compendium of the subject that we know.

## LITERARY NOTES.

MR. EDWARD ARNOLD has just published a small book entitled "Elementary Physiology for Teachers and Others," written by Dr. W. B. Drummond, Lecturer to the Edinburgh Provincial Training College. It is intended as an introduction to the subject for teachers in training who are attending lectures on hygiene. The aim of the writer is excellent, but we doubt very much the real value of such a book, especially when we find it stated that "sodium chloride, or common salt, is the most abundant mineral salt" in the body. Again, the illustrations in many instances are not all that might be desired. Altogether, there is a certain amount of scrappiness about the whole book which seriously detracts from its value as an aid to the acquisition of even an elementary knowledge of physiology. The price of the book is 2s. 6d., and its production is decidedly artistic.

\*\*\*

FROM Messrs. E. and S. Livingstone, Edinburgh, comes an old friend in the form of "Deuteronomy Smith" (price 1s. net). This *brochure* narrates in biblical fashion the doings of an Edinburgh medical student. It is full of wholesome humour, and a pleasant hour may be spent in reading the book, which contains a large number of comic illustrations. The present issue is said to be a new edition. At all events the book seems even still to find a ready sale, although many of the persons and positions referred to in its pages have long since ceased to exist.

\*\*\*

WE have been favoured by Mr. H. K. Lewis, of 136 Gower Street, London, with a copy of a Medical Ledger, which has been designed to meet the requirements of the busy practitioner. After a careful examination of the book, we can safely assert that anyone who wants a simple and compact system of bookkeeping will find it here. The plan consists of a combination of Day Book and Ledger, the first part being set out for daily entries, and the second part for monthly and yearly totals. In each case spaces are provided for record of payments. The Ledger has been so arranged that the labour involved in bookkeeping is reduced to a minimum, a consideration that is always of first importance to members of a busy profession. It can be commenced at any date, and is intended to last a year, but in many cases would be serviceable for a longer period. A copy will be forwarded for inspection to intending purchasers on approval, if desired. The book is of handsome quarto size, and is sold for the modest price of 6s. net.

## LABORATORY NOTES.

### DIAMALT AND COD-LIVER OIL.

THE malt extract prepared by the British Diamalt Company (11 and 13 Southwark Street, London) is well known for its purity and its high diastatic power. Taking advantage of the excellent way in which Diamalt blends with a high percentage of cod-liver oil, the company have produced two new preparations containing respectively 15 per cent. and

33½ per cent. of the oil by weight, or 20.3 per cent. and 41.7 per cent. by measure. We have estimated the amount of oil in these two preparations, and find that the statements as to its amount are fully borne out by our analyses, the actual percentages of cod-liver oil found in the samples being 18.2 and 33.8 by weight respectively. It might be thought impossible to conceal so large a proportion of the oil as one-third, but this is not the case, and in neither of the preparations is the taste of cod-liver oil evident to our palate. Both preparations may truthfully be described as "delicious." The pleasant taste combined with a high diastatic power, and a large percentage of oil will certainly render them most acceptable as adjuncts to therapeutics and popular with patients. In addition it may be added that these preparations are free from foreign flavouring substances and preservatives.

### CAPSULES DE BROMIASE (COUTURIEUX).

BROMIASE, a combination of bromide of potassium and levrine extractive, is an interesting product in that it enables us to administer the bromide in large doses for a length of time without the production of the characteristic cutaneous manifestations of "bromism." It has long been recognised that bromide eruptions are most apt to occur in presence of disordered digestion and intestinal fermentation, and it was this knowledge that prompted M. Couturieus, the well-known Paris chemist, to associate the bromide with a powerful gastro-intestinal disinfectant such as levrine extractive, a highly concentrated form of active yeast.

There is ample clinical evidence to justify the claim that the bromide administered in this form is comparatively free from any tendency to cause bromism, and, this being so, the combination will be found of service in all treatments into which bromine enters.

Bromiase is put up in sugar-coated ovoid tablets containing 8 gr., which are easy to swallow, and are quite free from taste.

### CAPSULES DE IODASE (COUTURIEUX).

IODASE is a combination of iodide of potassium and levrine extractive, and the action of the latter on the digestive tract is such as to avert the phenomena of iodism in the same way as it does in respect of bromine. Like its congener bromiase, it is put up in the form of sugar-coated ovoid tablets, each containing 8 gr. of potassium iodide. The London agents for both preparations are Messrs. Roberts and Co., New Bond Street.

## NEW INSTRUMENTS.

### THE SHAW INHALER.

WE have been favoured by Messrs. Macpherson and Co., of 89 Farringdon Street, London, with a sample inhaler jug which seems to be excellent in all details. Manufactured of thin porcelain, it is so constructed as to fit the face accurately. It is graduated both inside and outside with guiding lines so that the temperature may be regulated by adding more or less cold water to the standard amount of boiling water placed in the bottom of the vessel. It is a workmanlike little appliance, and is sure to be widely used if only its virtues become known to medical men and others who are interested in the scientific and practical equipment of the sick room.

SIR WATSON CHEYNE, BART., F.R.S., F.R.C.S., and Dr. Purves Stewart have been appointed Consulting Surgeon and Consulting Physician respectively to the Central London Throat and Ear Hospital.

THE Unionists of the Edinburgh and St. Andrew's Universities have secured a suitable candidate in the person of Sir Robert Finlay, K.C., G.C.M.G. Sir Robert represented the Inverness Burghs from 1885 to 1892, and again from 1895 to 1906. As a law officer of the Crown, he has held the posts of Solicitor-General and Attorney-General.

# SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

*Specially compiled for THE MEDICAL PRESS AND CIRCULAR.*

[SPECIALLY REPORTED FOR THIS JOURNAL.]

**A Critical Inquiry into the Cause of Internal Rotation of the Foetal Head.**—Paramore (*Journ. Obst. and Gyn. Brit. Emp.*, XVI., 4), after criticising the views of other writers, gives his own theory. In cases in which flexion is good, the point of impact of the advancing pole of the foetal head (vertex) with the pelvic floor is in the region of the coccyx. It is against this part of the pelvic floor that the vertex of a well-flexed head, be the forehead posterior or anterior, first impinges, and which first resists the head's further advance. In consequence of the continued downward foetal thrust, descent of the pelvic floor begins at this region of primary impaction, the coccyx becomes more sloped downwards and forwards, and forms an inclined plane, down which the vertex is pressed. When the forehead is behind, it is easy to understand how it falls into line behind the advancing vertex, and comes to occupy the middle line posteriorly, for the transverse diameters of the pelvis become diminished, whilst the antero-posterior becomes increased as the outlet is reached. When the forehead is anterior, the mechanism of its rotation posteriorly is more difficult. In these cases in which the head is well flexed, just as when the forehead is posterior, the vertex first meets the pelvic floor in the region of the coccyx, which, as before, becomes inclined downwards and forwards, and forms a plane along and down which the vertex is pressed. The vertex, therefore, is forced to occupy a lower yet more anterior position—that is, it is forced to approach the symphysis. Owing to the direction of the coccyx being continued by the ano-coccygeal raphe, further descent of the vertex can only occur in conjunction with its further projection forwards towards the symphysis. This can readily occur in occipito-anterior positions, as extension can and does now begin. But in occipito-posterior positions such movement is resisted by the chin already being in close contact with the chest, and thus the tendency for the vertex to advance towards the pubic arch compresses the forehead in a direction obliquely upwards, with a force proportionate to the force of descent, against the antero-lateral wall to which it was opposed before the movement began. Descent of the forehead is prevented by the tendency to advance of the vertex, nor can it ascend owing to the chest of the foetus being thrust down with the same force against the chin of the child. Since the vertex tends to descend, and cannot do so if the forehead maintains its place, and since the forehead cannot move upwards owing to the chest and chin, either extensive moulding must occur or the forehead must move along the line of the resultant of the two forces acting upon it, and since the transverse diameter of the pelvis is greater than the antero-posterior at the level at which the forehead lies, it follows the line of least resistance, and glides in the direction of the resultant of the two forces into the transverse diameter. The movement of the forehead into the transverse diameter of the pelvis allows the cranial axial line, about which internal rotation takes place, to advance towards the symphysis, for the forehead occupies an eccentric position in relation to it—that is to say, the distance between the forehead and the cranial axial line is greater than the distance between the side of the head and the same line. This advance of the upper part of the cranial axial line and the lower part being forced forwards by the tension and inclination of the pelvic floor, determines a lesser resistance between the side of the foetal head and the sacrum than exists between the forehead and the lateral pelvic wall; when the head has descended and the forehead comes into conjunction with a diminishing transverse diameter and an increasing antero-posterior diameter, the forehead tends to follow the line of least resistance and continues the rotatory

movement, so that eventually it rotates into the hollow of the sacrum, whilst simultaneously the occiput turns to the front. When, however, the head is not well flexed, the same mechanism cannot occur. The forehead being much lower in the pelvis than when flexion is good, the occiput must be situated more posteriorly in the oblique diameter. As the foetus descends, the anterior inter-parietal region cannot so easily cause descent of the pelvic floor, because it is more obtuse than the vertex, and its descent is resisted by a correspondingly large area. Nor can the lateral movement of the forehead occur, because, from its lying at a lower level, it has to rotate into a smaller transverse diameter than when situated high up, as in the case of good flexion, and, further, because the diameters of the foetal head concerned in such rotation are the bi-parietal  $9\frac{1}{2}$  cm. as before, but the sub-occipreg.  $9\frac{1}{2}$  cm. is replaced by the occ.-frontal 12 cm. Thus the change from occipito-posterior to the occipito-anterior results from the forehead being rotated backwards more than the occiput being rotated forwards. It depends on the flexion of the head bringing the vertex against the pelvic floor while the forehead is still at a high level in the pelvis, and still in relation to the large transverse diameters, and it further depends on the screw-like character of the pelvis, by which the greater diameter at the brim is transverse and gradually changes so that at the outlet it has become antero-posterior. F.

**Vaginal Cæsarean Section, with Report of Four Cases.**—Spriggs (*Amer. Journ. of Obst.*, LX., 4). Eclampsia has been, and probably always will be, the chief indication for this operation. Authorities are agreed to-day that, given a case with eclampsia, the safest thing for the woman and child is immediate delivery. Everyone realises the danger of sepsis from manual dilatation. In vaginal section the vagina can be rendered as aseptic as for any vaginal operation, so that the danger of sepsis is reduced when this operation is performed. In a case of placenta prævia, delivery can be effected more rapidly by this method than by either manual or instrumental dilatation, because the major part of the operation is completed before the cervix or uterus is opened, and then it is only a matter of a moment to make the incision up into the anterior wall of the uterus and manually separate and extract the placenta and the child by version or forceps. The dangers of the operation are the possible injury to the bladder and opening into the peritoneal cavity when a posterior incision is made. The operation and delivery can be done in from 10 to 15 minutes, and the repair in from 20 to 40 minutes, with a minimum amount of shock to the patient. The author describes the *technique* followed in his cases, and gives a short note of each case. F.

**Cervical Cæsarean Section.**—Lewis (*Amer. Journ. of Obst.*, LX., 4), after an extensive survey of the literature, remarks that he has collected 102 cases done since, and including Frank's first one in 1906. Of these women, 9 died, a maternal mortality of 8.8 per cent.; of these 104 children, 9 died, an infantile mortality of 8.6 per cent. In the majority of cases the main indication of the cervical operation instead of the ordinary Cæsarean section was the suspicion of infection. The main question as to the value of this operation depends upon how likely we are to have infection following non-aseptic conditions before entrance into hospital. Since most of the operators open the peritoneum and close it with permanent or temporary sutures before opening the uterus, there is here a large chance of infecting that cavity when the infected contents of the uterus are poured into the

wound. Close examination of the results does not make them appear as brilliant as the enthusiastic advocates of cervical Cæsarean section maintain. Fourteen of the cases were operated upon transperitoneally, and were therefore supposed to be aseptic. Forty were probably aseptic before operation. In such cases ordinary Cæsarean section has a mortality of only 4 per cent. The peritoneum was cut or torn accidentally in 8 cases. The bladder was injured in 3 cases; 42 of the cases may have been infected beforehand because of prolonged labour and examinations of uncertain cleanliness, early rupture of the membranes, or fœtor of the amniotic fluid. In only eight cases was there surely infection before operation. There was severe infection after labour, causing death in 5 cases, not causing death in 3, and less serious, mostly circumscribed, in 6—a total of only 14 cases which gave evidence after operation that the fear of infection was well founded. Cervical Cæsarean section is a more difficult operation than the other form; it requires deep dissection into extensive connective tissue spaces, and admittedly, in the probable presence of infection, it often involves considerable difficulty in extraction of the child, and leaves the uterus in an abnormally fixed position. For clean cases it cannot replace the ordinary operation, and for cases of possible previous infection it offers no better chances than the classical operation, with careful damming of the peritoneal cavity against the contents of the uterus and tight suturing of the uterine walls.

**Epithelioma of the Vulva.**—Ballock (*Amer. Journ. of Obst.*, LX., 4) gives the history and describes a case of this, and draws the following conclusions:—The predominating type is the squamous-celled. In the majority of cases the exact starting-point cannot be determined; it may develop in the labium majus or minus, or the clitoris, probably in the order named. The ulceration is peculiar in its mode of extension. Starting in the labium, it will spread in an upward direction and involve the clitoris and prepuce, the vestibule and the opposite labium; occasionally the mons veneris is involved. The spread is never towards the vagina, and very rarely to the skin of the thigh or abdomen. Irritating discharges from the vagina or uterus are liable to cause cancer. Pruritus vulvæ should be cured, as the irritation incident to this disease may cause cancer of the vulva. The earlier and more thorough the operation the better the prognosis as to complete eradication. Even if the disease involves only one side, the glands on both sides should be removed, and an effort made to determine the state of the pelvic glands.

## MEDICAL NEWS IN BRIEF.

### The Seventeenth International Congress of Medicine—London, 1913.

A MEETING of the National Committee for Great Britain and Ireland of the International Congress of Medicine was held at the Rooms of the Medical Society of London, on Thursday last, November 25th, Dr. F. W. Pavy, F.R.S., in the Chair.

Mr. D'Arcy Power read a report on the Sixteenth Congress at Budapest, in which it was shown that the British contingent numbered 94, and that the meeting was most successful in every way. At the Congress it was decided to appoint a permanent Committee consisting of the Presidents and Hon. Secretaries and some members of the various National Committees, with a president and a paid secretary. Dr. Pavy was appointed the first President of this National Committee.

Dr. Pavy then notified to the meeting the acceptance at the Budapest meeting of the invitation of the National Committee of Great Britain and Ireland, with the approval of His Majesty's Government, for the next Congress, in 1913, to be held in London.

Arrangements were then made for forming a General Committee to undertake the organisation required for the London meeting, and after passing a vote of

thanks to the Medical Society for the use of their rooms, the meeting of the National Committee adjourned.

The Hon. Secretaries, Mr. D'Arcy Power and Dr. Clive Riviere, would be glad to receive the names of any who are interested in the forthcoming Congress to be held in London.

### Cancer Research.

LORD CHEYLESMORE, in answer to questions at the Court of Governors of the Middlesex Hospital, held on the 25th ult., makes it clear how the quarter of a million sterling left by the late Mr. Harry Barnato will be spent. The money was left to form some charity in the nature of a hospital. The trustees have decided to found with the money a cancer institution, which, while distinct and self-supporting, will be administered by the Weekly Board and secretarial staff of the Middlesex Hospital. The funds of the hospital will, however, be kept separate from those of the bequest. The new cancer buildings are to be built close to the hospital, and besides laboratories will house patients, and there will be sufficient money to increase the number of those who are engaged in the research work. But it is to be clearly understood that the support of the present cancer department of the hospital will not be borne by the funds of the new institution.

### The Irish Medical Schools' and Graduates' Association.

THIS Association held their autumn dinner at the Hotel Cecil, on November 24th. The chair was taken by Dr. Mouillot (the President), and some two hundred were present. The usual toasts were proposed by the President. Dr. McManus gave "The Guests," which was responded to by Lord MacDonnell, K.C.V.O. The speech for the health of "Our Defenders" was made by Dr. J. Gubbins Fitzgerald, and was replied to by Sir Alfred Keogh, K.C.B., the President-elect of the Association. An interesting presentation was then made by the President, who, on behalf of the Society and himself, gave an illuminated address to the retiring Secretary, Dr. T. Hobbs Crampton, for his services to the Association during the last seven years. Sir Francis Fleming, K.C.M.G., delivered the introductory remarks to the toast of "The Association." The response was made by the President, who, in the course of his comments, said the objects of the Association were to have a meeting-place for the Irish graduates, and to hold a watching brief on their behalf.

The President's health was called for by Dr. Harry Campbell.

Songs and yarns between the toasts made a very enjoyable evening.

Among those present were Sir Charles Cuffe, K.C.B., Dr. Cambell Boyd (Hon. Secretary), Dr. Palisson Armstrong, T. J. Crean, V.C., W. P. Kennedy, H. Pollen.

### Royal College of Surgeons in Ireland—New Fellowship Examinations.

THE following regulations were adopted on November 18th:—

The Examination for the Fellowship is divided into two parts, viz.:—The Primary and the Final.

The subjects of the Primary Examination are—Anatomy, including Dissections, Physiology, and Histology. The Examination is partly written, partly *viva voce*, and partly practical. Candidates must pass in all the subjects at one Examination.

The subjects of the Final Examination are—Surgery, including Surgical Anatomy and Pathology. The Examination is partly written, and partly *viva voce*, and includes the examination of patients, and the performance of operations on the dead body. Candidates must pass in all the subjects at one Examination.

### King's Bench Division.

BEFORE Mr. Justice Channell and a common jury the hearing was continued of the action by Miss Mary Jane Stephens, residing at Crouch End, against the Dowsing Radiant Heat Company, Limited, for damages for personal injuries.

The plaintiff sustained burns, and it was alleged that this was due to the high frequency electric treatment which she underwent at the defendants' premises. The defendants denied negligence.

The plaintiff underwent the treatment when she was suffering from indigestion.

Dr. C. H. Langford said the plaintiff consulted him with reference to the high-frequency treatment, and he advised her to undergo it. The treatment, if properly administered, was recommended by the medical profession. The wounds on the legs were consistent with electrical burns.

Mr. Norman Craig said he did not contest that the wounds were caused by the treatment.

Cross-examined, the witness said that the high frequency treatment was administered in various parts of the country and in London.

Dr. Lewis Jones, of Harley Street and of St. Bartholomew's Hospital, said he had made a special study of medical electricity. In his opinion high-frequency required special skilled administration. He found that Miss Stephens' injury was caused by serious sparking. He found that the braid on the plaintiff's skirt had metal threads on it, and the contact could have been set up in that way and the burns caused in that way.

Cross-examined, the witness said the system was sometimes applied by nurses, but his view was that it should be only administered by duly qualified medical men. He did not think the accident could have occurred if there had been no tinsel braid on the skirt.

The witness added there must be contact with earth or the pole of the apparatus before danger arose.

For the defence Mr. Norman Craig contended that there was no case of negligence, as it was admitted that a state of things arose which had not come within previous experience.

Nurse Crossfield gave evidence, and denied that the plaintiff complained of pain during the time she was submitted to the treatment.

The jury, after considering for an hour and a half, returned a verdict for the plaintiff with £60 damages. Judgment was entered with costs.

His lordship said that there was nothing to complain of with regard to the defendants, the occurrence being more of an accident than anything else.

#### Dublin University Biological Examination.

THE opening meeting of the 35th Session of the Dublin University Biological Association took place on Saturday night, 27th ult., in the Debating Hall, Graduates' Memorial Buildings, T.C.D. Dr. T. G. Moorhead, outgoing president, occupied the chair.

The President presented to Mr. A. F. B. Shaw (Sen. Mod.), B.A., the Medal of the Association, awarded for his paper, "Some Notes on Anthropology," and to Mr. J. M. S. Gericke the Purser Medal.

Professor W. H. Thompson, the newly-elected President, read his inaugural address, the subject of which was "The Physiology of the Pylorus."

The address was discussed by Professor Halliburton, F.R.S., Mr. A. B. Mitchell, Principal Mettam, and Mr. William Taylor.

#### Medical Sickness and Accident Society.

At the usual monthly meeting of the Executive Committee of this Society, Dr. de Havilland-Hall in the Chair, the Committee passed a resolution, expressing to Mrs. Clutton, widow of the late Mr. H. H. Clutton, F.R.C.S., for many years one of the Treasurers of the Society, their appreciation of the loss they have sustained by his death, and their sympathy with her in her bereavement.

A more than usually long list of sickness claims was considered, but although numerous, the claims are for the most part of a light nature and of short duration.

#### Scientific Investigation of Children's Development.

THOSE of our readers who are fathers of families may feel inclined to respond to the appeal for help just issued by the Child Study Society. The Society in its efforts to advance knowledge of child life, has been looking for scientific aid, and has now succeeded

in gaining the co-operation of Professor Karl Pearson. He has drafted a schedule for studying the factors influencing the life of the child. It is desired that the schedule should be filled in by heads of families, especially of the upper, middle, or professional classes. The number of the family need not be large, but particulars of mother and father, and at least two children are required. Unless the number of schedules sent in is large, it will not make worth while the subsequent investigation by Professor Pearson. The appeal is especially made to members of the learned societies, and to professional men and women, who should be interested in promoting a more scientific treatment of child life. To supply the particulars asked for will call for two or three hours' work. The schedules can be had from the Society's office, 90 Buckingham Palace Road, S.W.

#### Swansea Workhouse Operating Theatre.

At a recent meeting of the Building Committee of the Swansea Board of Guardians, a letter was read from the Local Government Board suggesting that the cost of erecting an operating theatre at the workhouse should be reduced from £1,017 to £600. Mr. C. T. Ruthen, architect, in response to a request, attended and said it would be impossible to reduce the cost in view of the conditions imposed by the Local Government Board and the installation of a steriliser and special electric lighting. It was resolved to write the Local Government Board asking them how they arrived at their figures.

#### Conviction of a Nottingham Nurse.

At the recent Nottingham and Notts Assizes, Elizabeth Gamble, described as a nurse, was convicted of administering a certain drug for the procuring of abortion. A murder charge was withdrawn, and the prisoner was sentenced to three years' penal servitude. The police gave evidence to the effect that the prisoner had been carrying on similar practices for the past twenty years, and that a daughter had died in her house under suspicious circumstances.

#### Society of Apothecaries of London.

THE Diploma of the Society has been granted to the following candidate, entitling him to practise Medicine, Surgery, and Midwifery.—T. A. F. Tyrrell.

#### Trinity College, Dublin.

THE following candidates passed the Final Medical Examination, Part II., Surgery, at Michaelmas Term, 1909:—Hilgard Müller and John W. Flood (passed on high marks), Beatrice M. Hamilton, Peter H. Lemass (æq.), Adams A. M'Connell, Robert E. Lee, Joseph E. N. Ryan.

Part II.—Medicine.—Adams Andrew M'Connell and Brindley H. Moore (passed on high marks), Peter H. Lemass, William R. Watson (æq.), Louis Trichard, Edwin B. Bate, Robert E. Lee, James D. Murphy, Hugh S. Metcalf, Charles H. Denham, William H. Hart.

Licence in Dental Science.—Arthur A. Campbell.

#### Royal College of Surgeons in Ireland.

THE following candidates passed the Primary part of the Fellowship Examination:—Arthur Chance, junr., O. J. Hanlon, H. J. Smyly.

The following candidates, having passed the necessary examinations, have been admitted Fellows of the College:—D. Adams, L.R.C.S.I., etc.; W. V. Copinger, B.Ch., etc., Dub. Univ., Captain I.M.S.; M. G. Dobbryn, L.R.C.S.I., etc.; J. B. Dordi, L.M. and S., Bombay Univ.; M. W. Falkner, L.R.C.S.I., etc., Captain R.A.M.C.; J. K. Freyer, L.R.C.S.I., etc., Orange, New South Wales; C. Greer, L.R.C.S.I., Melbourne; H. W. A. Kay, L.R.C.S.I., Pretoria; Miss K. F. Lynn, B.Ch., etc., Royal Univ.; F. McKee, B.Ch., etc., Royal Univ.; J. B. Moore, B.Ch., etc., Royal Univ.; C. E. Murphy, L.R.C.S.I., etc.; T. North, B.Ch., etc., Dublin; T. T. O'Farrell, L.R.C.S.I., etc.; H. R. C. Rutherford, L.R.C.S.I., etc.; W. S. Sharpe, M.R.C.S.Eng., etc., Major R.A.M.C.; C. Sullivan, L.R.C.S.I.; and W. R. Wilson, L.R.C.S.I.

## NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

J. P. TAYLOR.—Your communication came to hand as we were "at press."

LEX.—The question whether a workman should undergo an operation when he has received some injury at his occupation which incapacitates him or not, really depends on (1) The proposed operation, if of a simple character; (2) the patient's health, and (3) if the operation will terminate his incapacity. If so, then the courts will usually hold that the true cause of the incapacity to work is the refusal to undergo the operation, and not the primary injury nor the resulting injury and as a consequence, they suspend the compensation payments until after the operation has been undergone. Removal of a sequestrum of dead bone from the big toe is the sort of operation that would be enforced by the above procedure.

E. R. C.—Your paper is marked for early insertion. COLONIAL.—There is no nomination wanted for the Colonial Medical Service. The usual method of obtaining appointments is to write to the Under-Secretary of State for the Colonies, Downing Street, London, S.W., and ask for a form of application for the Colonial Medical Service. The Colonial Office list, gives as complete a collection of the British Colonial Possessions as there probably is in print.

DR. H. W. G. M.—Proofs of your paper will be sent you during the present week.

HÆMORRHOIDS.—Aloes is a valuable purgative scientifically used. When taken continuously in form of quack nostrums it often gives rise to piles. The victims then very often seek relief from "pile cures," most of which are coarse swindles.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, DECEMBER 1ST.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. L. Cheatle: Clinique (Surgical). 5.15 p.m.: Lecture: Mr. C. Ryall: Appendicitis in the Female. NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Medical Out-patient (Dr. T. R. Whipple); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 p.m.: X-Rays (Dr. H. Pirie).

THURSDAY, DECEMBER 2ND.

ROYAL SOCIETY (20 Hanover Square, W.).—8.15 p.m.: Ordinary General Meeting: Prof. A. W. Porter: Some Effects of Electrical Discharges on Photographic Plates.

NORTH-EAST LONDON CLINICAL SOCIETY (Prince of Wales's Hospital, Tottenham, N.).—4.15 p.m.: Clinical Meeting.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 p.m. Lecture: Dr. D. Drummond (Newcastle): The Causes and Treatment of Indigestion.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynaecological Operations (Dr. A. E. Giles). Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 p.m.: Medical In-patient (Dr. G. P. Chappell).

HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON) (Great Ormond Street, W.C.).—4 p.m.: Lecture (Medical): Dr. Poynton: Recurrent Periodic Jaundice.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.).—4.30 p.m.: Clinical Lecture: Mr. Stuart-Low: Cancer of the Throat—its Prevention and Treatment.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture: Baldness—its Causes and Treatment.

FRIDAY, DECEMBER 3RD.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital).—8.30 p.m.: Paper: Dr. Hugh M. Bayly: Laboratory Diagnosis of Syphilis. Discussion by Col. Lambkin, R.A.M.C., Captain Harrison, R.A.M.C., D. J. Ernest-Lane, and others.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.).—3.45 p.m.: Lecture: Mr. W. Wallis: Mouth and Teeth.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—10 a.m.: Clinic: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Operations.

Clinics: Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 p.m.: Medical In-patient (Dr. R. M. Leslie).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. R. E. Bickerton: Clinique (Eye).

ROYAL SOCIETY OF MEDICINE (LARYNGOLOGICAL SECTION) (20 Hanover Square, W.).—5 p.m.: Cases and Specimens by Dr. Dundas Grant, Dr. W. H. Kelson, Mr. H. Betham Robinson, Dr. Scanes-Spicer.

ROYAL SOCIETY OF MEDICINE (SECTION OF ANÆSTHETICS) (20 Hanover Square, W.).—8.30 p.m.: Paper: Mr. Bellamy Gardner and Dr. Salusbury Trevor: Lymphatism, with specimens and lantern illustrations.

SATURDAY, DECEMBER 4TH.

ROYAL SOCIETY OF MEDICINE (OTOLOGICAL SECTION) (20 Hanover Square, W.).—10 a.m.: Cases shown by Dr. Edward Law, Mr. Herbert Tilley, Mr. W. Milligan, Mr. Richard Lake, Dr. Albert Gray, Mr. Sydney Scott.

## Appointments.

CHEYNE, Sir Watson, Bart., C.B., F.R.S. Consulting Surgeon to the Central London Throat and Ear Hospital.

KIDD, F. S., M.B., B.C.Cantab., F.R.C.S. Eng. Assistant Demonstrator of Anatomy at the London Hospital Medical College.

LINELL, J. W., M.B.Cantab., Resident Medical Officer at the Mount Vernon Hospital, Hampstead, N.W.

MILLER, ARTHUR H., M.B.Cantab., M.R.C.P.Lond., Physician to Out-patients at the City of London Hospital for Diseases of the Chest.

QUICK, E. J. J., M.R.C.S., L.R.P.C.Lond., House Anæsthetist to the Royal Dental Hospital.

SLIGH, H. P., M.B., Ch.B.Aberd., Medical Officer of Health to the Samford Rural District Council, Suffolk.

THOMPSON, Sir William J., M.D.Dub., Registrar-General for Ireland.

WALLACE JOHN THOMPSON, M.B., B.Ch., B.A.O., R.U.I., Surgeon to the great Western Railway Provident Society at Bristol.

PRICE, FREDERICK W., M.D., M.R.C.P., Physician to the Great Northern Central Hospital, London.

## Vacancies.

Suffolk District Asylum, Melton.—Second Assistant Medical Officer. Salary £160, with board, furnished apartments, attendance, and laundry. Applications to the Medical Superintendent.

Royal London Ophthalmic Hospital (Moorfields Eye Hospital), City Road, E.C.—Curator and Librarian. Salary £120 a year, with lunch in the Hospital. Applications, to the Secretary.

Cancer Hospital (Free) Fulham Road, London, S.W.—Physiological Chemist to the Cancer Institute. Salary £350 per annum. Applications to the Secretary.

Kent County Asylum, Chatham.—Third Assistant Medical Officer. Salary £145 per annum, with board, quarters, attendance, and washing. Applications to Medical Superintendent, Chatham, near Canterbury.

City and County of Nottingham.—Resident Assistant Medical Officer. Salary £130 per annum, with apartments, board, washing, and attendance. Applications to G. Muncaster-Howard, Clerk to the Board.

## Births.

BRADDON.—On Nov. 26, at 283 London Road, Thornton Heath, Surrey, the wife of William V. Braddon, M.B., B.C.Cantab., of a daughter.

BURKE.—On Nov. 27th, at Devonport, the wife of Capt. B. B. Burke, R.A.M.C., of a daughter.

FOSTER.—On Nov. 24th, at 181 Banbury Road, Oxford, the wife of E. C. Foster, M.B.O.S., L.R.C.P., of a daughter.

SELOUS.—On Nov. 26th, at "Agre," New Milton, Hants, the wife of Cuthbert F. Selous, M.B., of a son.

## Marriages.

BONSEY-DYMOCK.—On Nov. 25th, at St. Peter's, Bedford, Edward, son of the late W. H. Bonsey, of Slough, Bucks, to Edina, Florence, youngest daughter of the late Archibald Dymock, M.D., M.R.C.P., J.P., of Louth, Lincolnshire.

HAILESTONE-CLARANCE.—On Nov. 25th, at Jinja, Uganda Protectorate, John Edward Hailestone, M.R.C.S., L.R.C.P., Colonial Medical Service, eldest son of Commander Walter Hailestone, R.N., of Cheltenham to Harriet Emily (Birdie) Clarence, eldest daughter of Charles Clarence, of Saffron Walden. (By cable.)

MAIN-MIDDLETON.—On Nov. 24th, at Holy Trinity Church, Sloane Street, London, S.W., Dingwell Main, F.R.C.P.E. of Hangchow, to Florence, youngest daughter of the late Clement Alexander Middleton, Bench of Gray's Inn, London.

## Deaths.

CLARK.—On Nov. 28th, after an operation, Mildred Mary Christie, the loved wife of Percy J. Clark, M.R.C.S., L.S.A., of 2 Spital Square, Bishopsgate, London, aged 43.

HINE.—On Nov. 20th, at Hillbutts, Wimborne, Samuel Daniel Hine, M.R.C.S., third son of the late Samuel Daniel Hine, of Ashill, Somerset, in his 76th year.

STOCKS.—On Nov. 27th, suddenly, at Walton, the result of an accident, Frederick Stocks, M.R.C.S.E., of 421 Wandsworth Road, London, S.W., aged 65.

## NOTES AND COMMENTS.

**Is  
King's Lynn  
Asleep?**

IN the year of grace 1875, an Act for consolidating and amending the Acts relating to public health in England was enacted by the Queen's most excellent Majesty, by and with the advice and consent of the Lords and Commons in Parliament assembled. By Section 80 of this Act, "Every local authority shall from time to time make bye-laws" about common lodging-houses, yet thirty-four years later, in 1909, King's Lynn, a town of 21,000 inhabitants, in the county of Norfolk, and a seaport to boot, has no such bye-laws. The result, as reported by Dr. F. St. George Mivart, to the Local Government Board, is serious, apart from one of the instances cited, where a room reserved for two couples, and so occupied the night before Dr. Mivart's call, had no screen or curtain. The question that will occur to every plain man is, why King's Lynn has been permitted to neglect its statutory duties as regards lodging-houses. What have the Local Government Board to say upon the point? But the sanitary dispositions of this sleepy town are hopelessly at fault outside as well as inside the lodging-houses, as is abundantly shown in other parts of the official report.

**The Drainage  
of  
the Town.**

A WATER-CARRIAGE system is in vogue in the populous quarters, but its effluent is not carried clear of the town. In the neighbourhood of the Ouse and its creeks numerous water-closets discharge upon the mud-banks. The sewers themselves open into the same waterways, which, by-the-by, extend a considerable distance into the town. The consequence is that the banks are foul, and decomposing matter floats up and down with the tide. Naturally, complaints of offensive odours are common, and they justify, without going further, the recommendation that the question of culverting the Purfleet sewer outfall should have early attention, and that steps should be taken to prevent the discharge of water-closet drains upon the foreshore and mud-banks. The town refuse is disposed of at a tip on the southern outskirts of the place, where the contents of the earth-closet pans are also deposited. The mound at the foot of this tip is kept down by a sort of Chinese practice, as anyone may remove refuse for garden purposes upon applying to the surveyor for permission to do so.

**Housing  
at  
King's Lynn.**

A DESCRIPTION of the housing of this Rip Van Winkle town, written some seventeen years ago, with one exception, applies at the present moment. Many of the streets are narrow, and in certain quarters there are courts

or yards thickly populated and entered by narrow passages. Many are surrounded by high walls, to the exclusion of sun and air. The houses themselves are often in bad repair and overcrowded. The exception—the only redeeming feature—is the paving of the yards, during the last few years, thanks to the efforts made by the Inspector of nuisances. As, however, the "yards" are only about five feet wide (the windows of a house looking on to a wall five feet away), the significance of the remarks relating to the exclusion of sunlight and the prevention of the free circulation of air wants no emphasis, and the recommendation of Dr. Mivart that the Town Council should give early, careful and systematic attention to the housing question in the borough will be endorsed by all fair-minded people. Some decisive action is clearly needed on the part either of the local or the central authority, or of both.

**Enteric  
at  
King's Lynn.**

THE sequel of this sanitary slothfulness is written large in the report to the Local Government Board and in the statistics of the town. During the last ten years 278 cases of enteric fever have been notified, with 36 deaths. This, of course, is merely the natural corollary to the foregoing series of facts. What, however, shall be said of the cases of enteric contracted at King's Lynn and carried elsewhere, both by land and sea? Such a Town Council as that of Lynn has a grave responsibility, for it keeps going what is nothing more or less than an infective plague spot within our shores, pernicious alike to the inhabitants of the town and the outside world. Medical officers of health, no matter how capable, energetic and tactful, will find it a herculean task to cope with such a conglomeration of evils, and to avoid being at loggerheads with the Sanitary Committee, for, with this last evil, all hope of getting sanitation carried on must, as the law is at present, be very slow.

**School  
Infection.**

THE question of school infection, which has been lately raised at Bristol and elsewhere, demands firm yet cautious handling. Broadly speaking, the spread of infection amongst a juvenile population is a risk that, however much it may be modified by forethought, must be regarded as inevitable. The systematic medical inspection of State schools is undoubtedly the greatest step hitherto taken towards the limitation of the spread of infective maladies. In this way many a doubtful scarlatinal throat, many a scabies case, and many a verminous head, may be excluded from the school environment. It is difficult, however, to imagine any system that would enable

the authorities to recognise and deal similarly with measles and whooping-cough. There can be no shadow of doubt that diphtheria has increased concurrently and progressively with the growth of compulsory education in the United Kingdom. Nor is it open to serious contradiction that many outbreaks of measles, mumps, and other acute specific infections have taken place in schools. Under these circumstances, there is much to be said in favour of the systematic disinfection of schoolrooms, the dust of which has been repeatedly shown to contain the organisms of tuberculosis and other pathogenic microbes. In places where it is not possible to adopt the counsel of perfection of the open-air school, there would be no great difficulty in cleansing the class-rooms at frequent intervals by the scientific application of antiseptics of recognised value.

## LEADING ARTICLES.

### DAMAGES FOR SCHOOL TYPHOID.

ALTHOUGH enteric fever is, happily, a diminishing disease, there yet remains a great amount of labour and investigation before sanitary science can hope to be within view of its final extinction. In spite of all that has been discovered and of all advances in practical sanitation, it must be confessed that the origin of a considerable proportion of cases of this infection cannot be identified. As time elapses, there can be little reasonable doubt that medical science will hold the whole problem of enteric fever, from the preventive as well as the ætiological and the curative standpoints, in the hollow of its hand. One has only to look back upon the advances that have been made within a comparatively few years in our own knowledge of facts regarding this baffling and dangerous malady. The recognition of the agency of water and milk in its transmission, for instance, was followed by the identification of its specific pathogenic micro-organisms, the discovery of the agglutination tests, surgical operation for perforation, preventive serum inoculation, the transmission of the virus by flies, by uncooked vegetables, and by shell-fish, and the retention of the bacilli by persons, acting as "carriers" long after recovery from an attack. In view of solid progress of this kind, it comes somewhat in the nature of a surprise to find legal proceedings being taken against the proprietors of a dairy farm for having infected certain of their customers through the milk supply. The facts of the case are sad enough in their disclosure of preventable distress and death that is inseparable from the tragedy of typhoid epidemics. A schoolmaster at Deganwy, North Wales, brought an action for damages against the executors of the late proprietor of Marl Farm, Emmanuel Jones, for breach of warranty in connection with the supply of milk to his schools. The plaintiff appeared to rely mainly upon the Sale of Foods Act, whereby, as a customer, he was entitled to believe he would receive a pure milk supply. The crucial point before the Court, therefore, was whether the enteric fever at the school was due to contaminated milk supplied from Marl Farm. The plaintiff and his daughter contracted the malady and recovered, but his wife

died; three pupils also took the disease. Out of 250 persons in the neighbourhood who took their milk from the implicated farm 24 suffered from typhoid fever. The first to be attacked, in February, 1909, was Mrs. Thomas, housekeeper to Emmanuel Jones; she was at first removed to hospital, but insisted, on March 16th, on returning to the farm, when partially recovered, and it was not until after her return, namely, April 3rd, that the school was attacked in the person of one of the schoolboys. The plaintiff, on opening the school in 1905, obtained certificates as to soundness of drainage, water supply, and of sanitary conditions of Marl Farm. The medical officer of health of the district, Dr. Travis, for some time attributed the outbreak to the defective state of the drains, but on June 8th he wrote to plaintiff: "At first we were unable to trace the infection which occurred, but subsequent events showed clearly that the contagion was carried to your school in the milk." There was no satisfactory explanation at the trial as to what were the "subsequent events" referred to, and it is a somewhat disappointing feature of the trial that Dr. Travis did not appear as a witness. Indeed, the difficulties with which those dealing with typhoid fever are often faced were shown in other aspects of the case. Sir James Barr, out of two samples of blood taken from Emmanuel Jones, who had visited his housekeeper in hospital, in one instance failed on laboratory examination to detect the bacillus typhosus, while in the other he himself found "evidence of slight infection," presumably by the agglutination test. Apparently on the strength of seeing the blood taken by Sir James Barr for examination Dr. John D. Jones certified that Emmanuel Jones was suffering from enteric fever. In Court he admitted that, although he did not personally believe in the accuracy of that diagnosis, he nevertheless certified to death from valvular disease of the heart, typhoid fever, and congestion of the lungs. For the defence it was argued that the outbreak arose from an outbreak at Llandudno Junction, and from infection conveyed (by rats) up the sewers and drains to the school. It was shown that there was a defective grease trap, that a drain ran under the floor of an extension of the school buildings, and that there was an open sewer in a lane near the school. The medical officer of the county, Dr. Meredith Young, stated, on the other hand, that the drainage system at the school was well planned and well executed. The jury found that the plaintiff, his daughter and the pupils contracted the disease from milk supplied from Marl Farm, and that his wife's infection was by "contact." They awarded plaintiff damages to the extent of £500. One of the points urged by the defence was, that out of 150 visitors at a hydro-pathic establishment supplied with the incriminated milk, only one took the disease. On the other hand, six servants were attacked, a fact pointing to some special modification of the bacilli in the case of the visitors. In the course of the trial it was frequently asserted that the old theories of infection by the agency of drains and by aerial carriage were exploded. While it may be at once conceded

that the vast majority of cases are due to water, milk and other food contamination, and to "contact," there may be possibly a fair margin of infection that, under special conditions, has been transmitted through the air. In our present stage of knowledge, at any rate, it would be wiser to bear in mind that such a possibility has not yet been finally disposed of.

#### A MODERN MIRACLE IN SHEFFIELD

Now that it is becoming recognised generally that the physique of the nation is a matter demanding national care, all essays in that direction command more than a usual share of interest. One of the first logical applications of the new gospel has been the increased attention paid to the welfare of children. Of the many manifestations of this solicitude, such as medical inspection, free meals and the Children Act, it is not our present intention to speak, but we wish to allude briefly to an organisation that has been already alluded to in these columns, namely, the open-air school for delicate or backward children, as carried out at Charlottenberg, London, and other places. An account has recently been sent us by an old and valued correspondent of a movement of that kind that has been successfully adopted in Sheffield. In a busy industrial population of that kind, the necessarily crowded and unfavourable environment must inevitably result in the production of a number of children who, by reason of anæmia, inherited taints of various kinds, want of good air, food, clothing and housing, are unfitted physically to reap the benefits of compulsory education, and who in later life swell the ranks of the unfit who form a permanent addition to the population of our reformatories, prisons, workhouses and asylums. The results obtained by the Sheffield Education Committee's open-air school at Whitby appear to be no less striking than remarkable and conspicuous. It is described in a special article in the *Sheffield Daily Telegraph*, under the heading, "Young Children for Old," with the sub-heading of "Sheffield Miracles." The writer says that wrinkles and old looks have been banished from the faces of its scholars. "As a result of its working," he continues, "there are children in Sheffield to-day who were never really children before. They went to the school looking more like old men and women, with wasted frames, wrinkled brows and sunken eyes, but, after four months' life in the open air, good feeding, and removal from the environment of the streets, they have become children." The open-air school may be regarded as an extension of the special provision made for special classes of defective school-children, the backwardness in this special instance being the result of physical defects, such as anæmia and malnutrition, produced by squalid surroundings, insufficient and improper food, and insufficient sleep. The chief features of the school are, good and plentiful food, little education, life and exercise in the open air, and a regular allowance of midday rest, with attention to personal hygiene and regular bathing. Under these conditions remarkable results have been

obtained, amongst which may be noted the addition of 11 lbs. and 12 lbs. to the body-weight in the four months. The open-air school is, of course, costly, but it seems more than likely that the rate-payers will find it, in the long-run, a wise insurance premium against the physical, mental and moral deterioration that casts upon the community the burden of supporting a large population of paupers, criminals and other social derelicts. In any case, the medical officer of the Sheffield schools, Dr. Ralph Williams, is to be congratulated on the enthusiasm with which he has inaugurated and carried out the scheme. To replace a white-faced and prematurely-aged juvenile population by a race of alert, eager and full-blooded children is, indeed, a feat of which any man concerned may be proud, and none the less so when his altruism goes hand in hand with the exercise of a noble and self-sacrificing profession.

#### CURRENT TOPICS.

##### Beecham's Pills.

THE case of *Beecham v. Martin*, in the Dublin Court of Chancery, has assumed an interesting phase, in consequence of the nature of the defence set up by the defendant. The plaintiff's charge is that the defendant had passed off and sold to the public as "Beecham's" certain pills other than "Beecham's." The defendant, while denying that he ever was guilty of the offence alleged, stated that Beecham's pills were composed mainly of powdered ginger and soap, with a small percentage of aloes, and that the prime cost of the ingredients of a box of 56 pills, costing retail 1s. 1½d., and advertised as worth a guinea a box, was about one half-farthing. The defendant further alleged that the plaintiff had for years been falsely advertising the pills as a cure for constipation, headache, dizziness, wind, pain and spasms in the stomach, pains in the back, restlessness, insomnia, indigestion, want of appetite, fulness after meals, vomiting, sickness of the stomach, bilious or liver complaint, sick headache, cold, chills, flushing of heat, lowness of spirits, and all nervous affections, scurvy and scorbutic ulcers, wounds, kidney and urinary disorders and other complaints. It was further pleaded that plaintiff by such false representation that his pills had curative and medicinal properties that they did not in fact possess, had disintitiled himself to the assistance of a court of equity. This line of defence, it will be remembered, is the same as that adopted by the defendant in the "Bile Beans" case, before the Scotch Courts. The final trial cannot come on for some time, and we, of course, offer no comment while it is *sub judice*.

##### Dublin Corporation and Health.

As our readers must be aware, Dublin is by far the most unhealthy city in the United Kingdom. Its death-rate not only surpasses all others in the Kingdom, but is one of the three or four highest among the great cities of Europe. Outside Russia, indeed, it probably enjoys an inglorious pre-eminence. In our columns a few weeks ago we noticed a letter dealing with the health of the city, which had been addressed to the Lord Mayor by

the Medical Officer of Health, Sir Charles Cameron. One would expect that, knowing the evil reputation their city possesses, the members of the Corporation would be anxious to do everything in their power to improve the sanitary condition of Dublin. Such an expectation would meet with grievous disappointment in the actual facts. Nevertheless, the callousness exhibited comes as a shock even to those who expect little from the Dublin Corporation. A special meeting of the Corporation was summoned for last week to deal with Sir Charles Cameron's letter. The meeting fell through, *because a quorum did not attend*. Half a dozen members are all who could be found to take so much interest in the sanitary affairs of the city as even to attend a meeting at the City Hall.

#### Members or Licentiates?

IN our two last issues we published letters suggesting that the Irish and Scottish Colleges of Surgeons should put themselves in line with the English College by granting diplomas of membership instead of licences, as at present. There is no doubt that much confusion is caused in the lay mind by the multiplicity of medical titles, and Irish and Scottish licentiates practising in England suffer a certain disability in that the title of licentiate seems to suggest some inferiority to that of member. Any movement tending toward the simplification of titles deserves the support of the profession, and it seems to us that if the licentiates of the Irish College really want the other title, they cannot hope for a better opportunity to press their claim than the present. In the difficulties that face the College its strongest asset is the loyalty of its Fellows and Licentiates. That loyalty exists, and may be counted on not to fail, but it should give the Licentiates a claim to press their demand for a change of title, if they are truly serious in the matter. The corporations are, however, conservative bodies, and will certainly not move unless a change is desired by the great body of the licentiates. Some years ago a petition to the Royal College of Surgeons of Edinburgh was signed by some 500 licentiates, in response to an appeal issued by the Association of Medical Diplomates of Scotland.

#### The Ethics of Anti-Vaccination.

THE action in which Dr. Martha Adams sued for damages for an alleged libel in *Vanity Fair* ended on Friday last with a verdict for the plaintiff, with nominal damages. The most interesting episode in the trial was formed by the evidence of the Hon. E. A. G. Pomeroy, the writer of the article objected to. According to the *Times* report, Mr. Pomeroy stated that, in the main, he believed that freedom from vaccination would spell bankruptcy to half the medical profession. He described doctors as "fee-hunters," and being asked if he meant that doctors pretended to believe in vaccination because they wanted fees, he replied: "Well, poor fellows, they have got to live." Mr. Pomeroy did not go on to explain that, with the rarest exceptions, the large section of the profession who derive no sordid benefit whatever from vaccination, and have no interest in supporting a deadly fallacy, prove their belief in the efficacy and harmlessness of the operation by having their own

children vaccinated, and re-vaccinated; and he did not explain how the training of a doctor thus converts the average man of superior intelligence into an anti-human wretch capable for paltry gain of sacrificing the health of those nearest and dearest to him in pursuit of his nefarious aim. All this and other deductions from his facts Mr. Pomeroy no doubt reserves for future occasions. When he completes his indictment of the profession he will no doubt say whether he is following the spirit of the advice which he stated he had suggested to parents, namely, that, although "lying was wrong, if you could not get what you had a right to in any other way, you were entitled to do so." The formulation of this high ethical standard cannot fail to supply poison to the sting with which anti-vaccinationists so effectually assail a guilty and trembling profession!

#### The Dental Jubilee.

THE dinner given by the President and the Council of the College of Surgeons of England on Thursday last to celebrate the jubilee of the dental diploma proved an interesting and memorable gathering. It was unfortunate that, owing to advancing age and the inclement weather, the sole survivor of the memorialists who in 1855 first urged upon the College the desirability of founding a dental qualification, was unable to be present. Otherwise it was a notable assembly, including many of the men to whose labours the establishment of dental surgery as a legitimate curative speciality has been due. The chief feature of the evening was the speech of the President, Mr. H. T. Butlin, in proposing the toast of the "Dental Profession." It is difficult to understand how, without literally an enormous amount of study, Mr. Butlin could have made himself familiar, not only with the history of the dental movement beginning some sixty years ago, but also with the personalities of the chief actors in that history. His narrative was, although concise, quite complete, and it had throughout much of the character of a human document, and it was touched with so nice a sense of humour that it proved deeply interesting as well as entertaining to the whole of his large audience. Mr. Butlin illustrated his sketch of the progress of dental science by reference to three standard text-books, those of Mr. Jones, Mr. Sewill, and Mr. Collyer—with each of which he was evidently well acquainted. After dinner, an adjournment was made to the room set apart for the dental museum, now handed over to the College by the Odontological Society, on its incorporation in the Royal Society of Medicine. Mr. Butlin stated in the course of his speech that this is now unquestionably the finest dental museum in the world.

#### Medical Arrangements at Unions.

THE Sheffield Guardians do not seem to be particularly happy over the medical arrangements connected with the Workhouse. At a meeting of the Guardians, held Wednesday, December 1st, 1909, a resolution was moved, and carried, "That all questions as to the duties of the medical officer of the Workhouse, as to the assistance rendered to him, and the Workhouse itself, by the hospital medical officer, and the cost of that assistance, be referred to a special committee for consideration

and report." An amendment was moved, but lost, "That the Local Government Board be asked to hold an inquiry into the manner in which the duties of the medical officer of the Workhouse are being carried out, and the extent to which they can be properly performed by the medical officer of the hospital." The mover of the amendment described the medical officer's visits as "a sort of hurricane visit to the Workhouse each day." As far as one gathers from the report of the meeting of the Guardians, it seems that they are under the impression that the medical officer to the Workhouse looks to the resident medical staff in the Union Infirmary to do his work for him, when unable to do it himself. The Guardians contend that the medical officer to the Workhouse, or his deputy, were altogether responsible for all the duties in connection with attendance upon patients in the Workhouse, and that the resident staff have quite enough to do to attend to their own duties; the general practical point is the two departments are altogether independent of each other, and should be kept so.

#### Preservatives in Cream.

THE question of the use of preservatives in cream is of importance, in view of the fact that cream is so often relied upon in various conditions of malnutrition; and the subject has, therefore, been frequently noticed in these columns. The presence of an excess of boron and other preservatives converts the cream into a poisonous compound, and this abuse cannot at present be checked without statutory authority. Medical men can only put their patients on their guard, and advise them to obtain their cream, when possible, from one or other of the firms that give a guarantee of its purity. Under the direction of Dr. Collingridge, twelve samples were obtained recently in order to determine the extent to which preservatives are used in preparing cream for retail in the City. With the exception of two, they all contained boracic acid preservatives. In three cases only, however, was the amount found in excess of the limit, 0.25 per cent., recommended in the Departmental Committee's Report, to which reference was made in our last note on this subject. The fact, however, remains that the purchaser has no means of ascertaining the amount of preservative present, for although in five samples the presence of boric acid was notified by label, and others were described as "preserved" cream, in no case was more definite information afforded.

#### Women as House Surgeons.

THE Committee of the Manchester Infirmary have adopted the report of their sub-committee elected to inquire into the question of the appointment of women to resident posts. Their decision is adverse to the admission of women to such offices, and it is worth while giving a summary of the reasons alleged for this opinion. The Committee found that no male patients, and very few female patients preferred to be attended by a woman, and they did not learn that there was any desire among the patients for a change. They further expressed the opinion that medical women ought not to have charge of male wards. In the surgical wards there are

things to be done for men which a woman practically cannot do, and in both medical and surgical wards there are things to be asked and told which a woman cannot ask and would not be told. A medical woman is not, therefore, as useful an officer in general hospitals as a medical man. The Committee noted that medical women have not generally been appointed to resident posts in general hospitals with medical schools attached; the Royal Free, London, one of the rare exceptions, has as one of its main objects the education of medical women. In their own special case the Board of the Manchester Infirmary find that to accommodate women house-surgeons would entail substantial building additions involving heavy expense, and they do not feel justified in incurring this for the purpose of an experimental change which could not be of advantage to the institution.

### PERSONAL.

THE KING has been pleased to appoint Mr. A. J. Ram, K.C., a member of the Royal Commission on Vivisection, to be Chairman of the Commission in the place of the late Viscount Selby.

THE PRINCE OF WALES last week sent gifts of pheasants to Guy's and St. Mary's Hospitals.

LADY CONSTANCE HATCH, on December 2nd, opened a bazaar at the Royal Ear Hospital, Soho, in aid of its funds.

SIR DONALD MACALISTER, as President, occupied the chair at the 90th Session of the General Medical Council at its Oxford Street offices.

DR. BASHFORD will, it is announced, be present at the *conversations*, and will demonstrate some of the recent cancer researches at the Polyclinic, Gower Street, on Friday next.

DR. G. A. HERON, the Treasurer and Chairman of the Council of the London and Counties Medical Protection Society, addressed the members at the special general meeting on November 24th last.

DR. W. H. RIVERS, Mr. J. H. Parsons, and Dr. W. W. Watson gave evidence last week before Sir Francis Mowatt relating to colour vision at sea at the special inquiry being held by the Board of Trade.

THE Medical School of King's College Hospital (separated by the King's College, London (Transfer) Act) has been admitted as an independent body to the status of a school of the University in the Faculty of Medicine.

PROFESSOR J. ROSE BRADFORD was re-elected Secretary of the Royal Society, in conjunction with Sir Joseph Larmor. Amongst those elected to the Council were Dr. W. H. Gaskell and Dr. C. J. Martin. Sir Archibald Geikie was re-elected President.

WE much regret to announce the death of Mr. Marcus Gunn, Senior Surgeon to the Royal Ophthalmic Hospital, Moorfields, and Ophthalmic Surgeon to the National Hospital for the Paralysed and Epileptic, Queen Square, W.C., which occurred at Hindhead on Monday week, November 29th.

THE action by Dr. Martha Adams, a medical inspector of schools at Twickenham, against Mr. Ernest Pomeroy, the writer of an article in *Vanity Fair*, criticising her conduct in the matter of vaccination, ended in the High Court on Friday last in a verdict for plaintiff, with one farthing damages.

## A CLINICAL LECTURE ON THE SYMPTOMS OF INTESTINAL STENOSIS.

By PROFESSOR A. MATHIEU, M.D.,

Physician to the Paris Hospitals.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE diagnosis of incomplete intestinal stenosis and the resulting symptoms of obstruction is often a matter of some difficulty at the onset, and their significance is very apt to be overlooked, so that the actual gravity of the patient's condition is not recognised and surgical aid is not obtained until the complete picture of intestinal obstruction presents itself. Now the prognosis in these cases is the graver the longer operative intervention is delayed. The early recognition of these states is, therefore, a matter of the greatest importance. From this point of view sufficient attention is hardly paid to the symptomatic significance of intestinal splashing and the phenomenon of pseudo-ascites.

Whenever there is narrowing of some parts of the digestive tract, wherever situate, the tendency above that spot to the production of certain symptoms is the same, viz.: retention of digestive fluids and hypersecretion, together with the retention of more or less flatus. We are, therefore, in presence of more or less dilated cavities, more or less filled with gas and fluid.

When the narrowing is situated in the pylorus the symptoms are familiar to us. We know that a patient with pyloric stenosis will present stasis hypersecretion with the accumulation of a large quantity of wind, either from fermentations or swallowed air. In such cases there is dilatation and gastric stasis.

The symptoms of intestinal stenosis are less pronounced and less well known. Let us take a case of stenosis limited to a part of the intestine high up. A lady, who had been examined six years previously and who had suffered from indigestion for a long time, complained of pain in the region of the stomach with occasional free vomiting. When fasting, marked splashing could be elicited in the umbilical region and below. The splashing was readily caused by shaking or digital succussion. This justified the conclusion that the stomach contained stagnant liquid and alimentary *débris*. Exploration by the aid of a tube, however, gave a negative result, so that one was led to suspect hour-glass stomach, but a more rational explanation would have been that the case was one of limited dilatation of the intestine, this conclusion being based on the observed fact that the splashing was very extensive, reached low down and gave a special note. On the case being operated on by M. Quenu, the obstacle was found to be situated in the lower third of the ileum where there was a circular stricture of fibroid tissue within which they discovered an osteoma, quite a curiosity in human beings, though it would seem to be fairly common in veterinary practice. In short, it was a case of dilatation of the upper part of the small intestine simulating dilatation of the stomach.

Nowadays, radiographic examination affords arterial assistance in the differential diagnosis of

hour-glass stomach and dilatation of the upper part of the small intestine.

On the other hand, we may meet with dilatation of the stomach independently of actual stenosis. For instance, a patient, about thirty years of age, was admitted with symptoms clearly pointing to ulcer of the stomach, viz.: pain, bleeding into the stomach manifested by melæna, tumefaction of the epigastric region, splashing sound on being shaken. At first we suspected juxta-pyloric ulceration with spasm and acute dilatation of the stomach, but, as in the case related above, introduction of the stomach tube gave a negative result. It turned out to be a case of dilatation of the transverse colon. Dilatation of the intestine lasting two days was followed by copious evacuation of the intestinal contents, and this in its turn was followed by spasm of the large intestine, that is to say, the spasm of the lower part now extended to the upper part of the ascending colon.

It follows that it is not sufficient to make out circumscribed or generalised splashing in the intestinal domain to justify the diagnosis of intestinal obstruction, consequent on progressive narrowing. Other symptoms must be present, and, in addition, the course of the subsequent developments must be conformable to this hypothesis.

Localised dilatations of the cæcum and ascending colon often constitute the earliest symptoms of gradual stenosis, in which event we get a syndrome that has been well described by Bouveret, of Lyons. This syndrome is met with in presence of progressive stenosis of the right curvature of the colon, and under these circumstances the mischief is usually an obliterating cancer.

During the acute attack the patient complains of sharp pain in the right flank. If we make an examination during the attack the abdomen is found to be swollen, more on the right than on the left side or over the middle line. It may even be possible to make out the dilated and prominent colon which may be the seat of well-marked peristaltic contractions. If we now have recourse to succussion we get splashing within the dilated colon, and this can also be provoked by digital succussion.

These attacks recur from time to time with intervals of from a few hours to two or three days. Between the attacks the cæcum and dilated ascending colon are no longer contracted and tense, but they are still dilated, and limited splashing may still be elicited. This syndrome is of great significance in respect of the diagnosis, and justifies our concluding in favour of stenosis, usually cancerous, of the right angle of the colon.

This is an example of the partial dilatation and circumscribed splashing which are met with in the intestine in presence of progressive stenosis.

These patients, however, have a tendency to general dilatation of the intestine with the production of symptoms of obstruction which, in time, merge into those met with in association with narrowing of any other part of the intestine, the ileo-cæcal valve, for instance. The only distinguishing feature is the existence of an initial period, plainly limited to dilatation of the cæcum, pointing to the existence of a limited obstacle at a particular and strictly defined spot in the large intestine.

We may leave on one side the cases in which we get circumscribed splashing as the result of partial twisting of a loop of intestine, and we will pass on to consider the symptomatology of extensive splashing in the intestine, usually accompanied by symptoms of pseudo-ascites.

Ricard brought before the French Surgical Society the case of a carpenter, admitted on account of serious abdominal symptoms of four days' standing. The attack had commenced with severe pain in the right groin coinciding with the appearance of a small tumour the size of a filbert. His medical man took it to be a case of strangulated hernia and reduced the tumour by taxis. The symptoms, however, persisted, the general state became more threatening, the pain got worse and vomiting supervened, in fact, all the signs and symptoms of acute obstruction as the result of strangulated hernia. The face was drawn, the eyes hollow, and the complexion cyanosed; there was diarrhœa and, as a matter of fact, diarrhœa motions are the rule in cases of incomplete stenosis of the intestine not only the acute, but also the gradually progressive.

The pain subsided in the course of a few days and the abdomen became soft, flat and indeed somewhat concave. There was an entire absence of the tympanites so commonly met with in cases of obstruction. The patient was much prostrated. The results of examination were as follows: Over the middle region of the abdomen, as well below as above the umbilicus, there was well-marked splashing on succussion, and when the patient was placed on his left side there was an area of partial dullness limited to the lower third of the abdomen on that side with, on the contrary, absolute resonance on the right side. When he was turned over on to the right side the dull area became resonant and the resonant area became dull; in fact, the symptoms pointed to the displacement of fluid inside the abdomen. Had it not been for the splashing sound one might have suspected ascites. These are the signs of pseudo-ascites met with in partial obstruction of the lower part of the small intestine. Laparotomy showed the existence of compression of the lower part of the ileum in the hernial sac.

In another case the patient, a lady, had been suffering from repeated attacks of very painful colic with well-marked abdominal distension and recurring vomiting. Finally, complete obstruction set in. In this instance no splashing sound could be elicited, although the loops of intestine were much distended. In point of fact the symptoms of pseudo-ascites are only met with in cases where there is comparatively little abdominal distension and accumulation of flatus, and this is easy to understand, because excessive distension of the intestine may prevent splashing and the sensation of moving liquid.

This pseudo-ascites was pointed out by von Litten in 1885 at the Berlin Medical Society in

a tuberculous subject, in whom they had diagnosed chronic peritonitis with ascites. At the autopsy they discovered no ascites, but well-marked intestinal dilatation.

In 1897 Pierre Delbet mentions having met with pseudo-ascites in two cases of incomplete stenosis with progressive intestinal obstruction, and he describes a sign which enables us to distinguish it from true ascites, viz.: the line of dulness is regularly horizontal in the latter, whereas in the others it presents areas of resonance dull to the inclusion in the intestine of gaseous collections.

The existence of the sound of moving liquid and shifting dulness at the lower part simulating ascites enables us, therefore, to recognise progressive stenosis of the intestine, and, within certain limits, to determine its situation. Nevertheless, the value of this sign is not absolute, although it constitutes an important diagnostic element when the history of the case, in other respects, is suggestive of the existence of progressive partial intestinal stenosis. It is, therefore, a sign to be carefully looked for, but which can only be relied upon when all the other symptoms, and the course of the case point in the same direction. We must not overlook the fact that intestinal splashing is a common symptom in certain forms of diarrhœa.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by: *Dr John F. H. Broadbent, Bt., M.D. Oxon., F.R.C.P. Lond., Physician to St. Mary's Hospital, Paddington. Subject: "The Prognosis and Etiology of Mitral Incompetence."*

## ORIGINAL PAPERS.

### THE OPSONIC METHOD. (a)

By HERBERT W. G. MACLEOD, B.Sc., M.D.  
EDIN., M.R.C.P. LOND., D.P.H. LOND. AND CAMB.

Physician, Western General Dispensary.

METCHNIKOFF, as we know, brought forward the theory of Phagocytosis several years ago as an explanation of natural and acquired Immunity.

Phagocytosis may be defined as the power possessed by certain leucocytes of taking-up, or ingesting bacteria. Those specially concerned in this process are the polymorphonuclear and mononuclear leucocytes, known also as micro- and macro-phages. This property of ingesting organisms is also possessed by the connective-tissues and endothelial cells of the body.

But before phagocytosis takes place, another process known as positive chemiotaxis occurs. It is an attraction exercised by bacteria on leucocytes. Following these two stages is a third one—that of intra-cellular digestion or disintegration of the organisms. By some this is thought to be caused by certain ferments which are known as "cytases." We have then (to recapitulate) the three stages of Chemiotaxis, Phagocytosis and Digestion which cause immunity.

Metchnikoff considered that immunisation was due to a stimulation of the phagocytes; but Wright has advanced a later theory based on that of phagocytosis. He is of the opinion that certain anti-bacterial elements are present in the blood—

(a) A Lecture delivered before the Worcestershire Medical Society followed by a Demonstration.

serum and that they act first on the bacteria and so alter these organisms that they can in consequence be more readily "ingested," or absorbed, by the leucocytes.

To these substances in the blood he applied the name "Opsonins," derived from ὀψωνεω, "I prepare food for."

Sir A. Wright does not consider that successful immunisation is caused by an increased capacity for phagocytosis of the white corpuscles, but to increased "opsonic" power of the serum. He and Douglas found, by experiment, that if bacteria which had not been under the action of serum were brought in contact with leucocytes which had first been washed in a solution of sodium citrate and then in physiologically normal salt-solution (that is to say one of 0.85 or 0.9 per cent. sodium chloride—which is approximately of the same specific gravity as the liquor sanguinis) the leucocytes ingested the organisms in a feeble and irregular manner. Some cells absorbed no bacteria, others only a few. If the strength of the salt-solution was increased to any extent, phagocytosis did not occur at all.

On the other hand, if the bacteria had been previously exposed to the action of blood-serum and were then brought into contact with leucocytes treated as before, every leucocyte rapidly took in many organisms; and this occurred even if the strength of the salt-solution was raised above the normal.

Artificial Immunity, as we know, is divided into "active" and "passive"; the former being produced by injecting directly into the patient (or the animal) living or dead organisms, or their toxins. Passive immunity is caused by injecting into the patient the serum of an animal which has been immunised by the active method.

The opsonic treatment is the active immunisation of the patient, by the injection of a vaccine, prepared from cultures of bacteria, preferably of recent growth. They are washed off in sterile normal salt solution, and this suspension of bacteria is shaken up for some time, so as to break up "clumps" and "chains." The vaccine is standardised, and all the organisms are killed at a temperature of 60° C. If proved to be sterile, by making subcultures, an antiseptic (such as weak solution of lysol, or carbolic acid) is added, so that 1 c.c. of the vaccine contains 200—or 1,000—million bacteria, or any required number of them. Tubercle vaccine is prepared from tuberculin ("T.R.") suspended in a lysol-salt solution, and the initial dose is about a twenty-thousandth of a milligram.

Bacterial disease is treated by injecting the corresponding vaccine, and, if possible, one freshly prepared from the patient. A stock solution may be used; and this, if kept under proper conditions, will be of service for a long time. Many of you, Gentlemen, have no doubt successfully employed serum-therapy in treating cases, and you may well ask what are the advantages of the Opsonic method over treatment by serum? We know that the latter has been most useful, in the form of Antitoxin, in cases of Diphtheria; it has also been successful in Tetanus. Serum injection causes passive immunisation in contra-distinction to vaccine therapy, which, as we know, is "active." The injection of serum for other diseases has on the whole been disappointing, and it has not been satisfactory in cases of Tuberculosis,—contrary to expectation. Com-

paring the two methods of treatment: in the one we have to judge the effects on the patient by clinical observations which may be very variable and deceptive, but on the other hand, we have the "opsonic index" to guide us in addition to symptoms manifested by the patient.

The "index" is a ratio of percentages. It is obtained by examining under the microscope a "blood-spread," suitably prepared and stained, and counting the bacteria which have been ingested by at least one hundred polymorphonuclear leucocytes, which have been acted on by anti-bacterial lements in the patient's serum. This number forms the "numerator" of the fraction. The "denominator" is the number of organisms (of the same emulsion) taken up by a hundred leucocytes subjected to the influence of the serum of a normal individual (or of mixed normal sera) similarly prepared and stained. The result of dividing the former "count" by the latter is the "opsonic index." The normal serum is taken as unity. It follows, then, that if the patient's serum gives a higher phagocytic count than the normal the index is high; if it practically coincides with the normal the index is normal; and if it is below the normal phagocytic count the index is correspondingly "low." A question that will naturally arise is "What information does the index afford us with respect to treatment and dosage?" It may be stated, generally, that an index below the normal (to the corresponding vaccine) indicates disease. There are certain conditions modifying this conclusion, which will be better known as our experience increases. But we must bear in mind that what Wright calls the "negative phase," occurs in many diseases: that is, a lowering of the index (temporarily) is attended by a subsequent rise; particularly is this so in tubercle. If this phase be followed by a steadily rising index, it is assumed that the case is improving under treatment.

With regard to dosage, the following observations have been made: a rise after injection with little alteration of the index for several days subsequently, indicates a small dose; a slight fall succeeded by a marked rise, points to a correct dose; and a fall followed by a further fall, means that too large a quantity has been administered. Or, to put it in other words: a moderate dose is followed by a short negative phase and succeeded by a positive phase lasting about ten days. A smaller dose has a positive effect rapidly, but this is not long maintained. An excessive dose has a negative phase which lasts a long time.

The opsonic treatment has already afforded good results; particularly so in diseases of the skin, due to staphylococcal and streptococcal infection. It has also been beneficial in cases of tubercle, both for diagnosis and for treatment. Cases of acne, furunculosis and erysipelas have given excellent results; and in instances of a mixed infection it is best to immunise against each organism. I have obtained good effects in protracted suppuration after a dental operation, the organisms in the discharge having been isolated bacteriologically; and I have a case of *Pyorrhoea alveolaris* under observation in which I think vaccine treatment will afford satisfaction.

It is a *sine qua non* that the correct technique be employed in taking the index. It should be estimated before using the vaccine, and subsequently, and it may be necessary to ascertain it frequently in severe cases.

In patients suffering from diseases of the skin caused by coccal infection the index need not be taken, and the results of treatment and the progress of the case may be watched by clinical observations alone. This applies chiefly to patients who exhibit superficial lesions, the symptoms being easily noted; but it is inapplicable to those diseases the progress of which cannot be so readily followed.

To estimate the index, we require to have washed corpuscles, a bacterial emulsion, the serum of the patient, and a normal serum as a "control." The corpuscles are obtained from normal blood run into a small tube containing a 1.5 per cent. solution of sodium citrate, to prevent coagulation. This is shaken up, and is then centrifuged. The red and white corpuscles sink to the bottom, and the supernatant fluid is pipetted off. Sodium chloride solution of 0.85 or 0.9 per cent. strength is next added to the corpuscles, and they are again centrifuged and the clear upper liquid removed. At the bottom of the tube a thin layer of leucocytes is seen to lie on the heavier red corpuscles. This upper layer may be pipetted off and put into another tube for use; or the two layers may be shaken up and utilised.

The bacterial emulsion (except in the case of tubercle) is made from fresh cultures in agar. They are rubbed up in 0.85 per cent. salt solution (or in 1.5 strength in certain cases); centrifuged to break up clumps or chains of bacteria; and if necessary, diluted.

The blood of the patient, and also that from a normal person, is received into curved "capsules" made under the blow-pipe from quill glass-tubing. The blood must first be allowed to clot. It is then centrifuged to separate the serum. By means of specially prepared pipettes fitted with rubber teats, a measured volume of washed corpuscles, and equal volumes of bacterial emulsion and of serum are successively sucked up, a minute bubble of air separating each. These are blown on to a clean slide and mixed by being drawn up and down the pipette several times. The fine end is then sealed in a flame, at a safe distance from the fluid, and placed in the incubator at a temperature of 37° C. for eight or fifteen minutes as may be necessary. During this period the leucocytes ingest the bacteria, which have been acted on by the serum.

The same procedure is gone through with both sera. The contents are blown on a clean slide, mixed, and then a small drop is placed at the end of another slide and spread by the edge of a piece of cigarette paper, or of gutta-percha tissue cut "square." A glass spreader may be made, having a slightly concave edge, or the end of a narrow slide may be used at an angle of 45° to push the drop of blood along.

The smear is then fixed with a saturated solution of corrosive sublimate, or by the vapour of formalin, and suitably stained. For tubercle-bacilli, the Ziehl-Neelsen method is employed, and for other organisms Carbol-Theonin-blue or Leishman's stain, a modification of Romanowsky's. In this case previous fixing of the film is not necessary.

The index is then estimated as already explained.

(A demonstration of the *technique* and apparatus was given, and stained specimens were exhibited under the microscope.

## ADHESIONS OF THE DIAPHRAGM.

By L. BASSENCE, M.D.,

Staff Surgeon, Berlin.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE physical examinations usually employed (inspection, auscultation, percussion) not infrequently give the inquirer only an indistinct idea of the position and movements of the diaphragm, and of the pathological changes of condition. Here the introduction of the Röntgen rays for diagnostic purposes, in regard to internal diseases, has made clear what was already known and imparted new knowledge. A glance at the illuminated screen shows sensible changes of position of the diaphragm, bilateral rise with increase in the contents of the abdominal cavity, whether meteorism, ascites, tumour, or physiologically pregnancy, a bilateral depression in acute pneumonia, unilateral rise in gaseous distension of the stomach, considerable increase in size of the liver, or unilateral paralysis of the diaphragm, unilateral depression in emphysema, and filling of the pleura with air or fluid.

Very much more important are the conclusions to be drawn as to the extent and character of the movements of the diaphragm afforded by the use of the Röntgen rays. I here recall that it was the fluorescent screen that first gave any satisfactory information regarding the normal inspiratory fall of the diaphragm, and that any change from this type came to be grasped and understood. Amongst the latter immobility of one-half of the diaphragm on inspiration—the so-called Williams' symptom—has gained the importance—not undisputed, however—of a sign of commencing tuberculosis of the apex.

Amongst the changes of character of the movements of the diaphragm, the atypical ones are of special interest. First among these are the visible flexions and kinkings of one or both leaflets of the diaphragm such as are quite frequently to be seen in advanced cases of pulmonary tuberculosis, when the inflammatory changes have reached the pleura of the lower lobe. In such cases the diaphragm shows the normal contour at the moment of pause, and it is only on deeper inspiration that one or more wave-like or tent-shaped bulgings out are to be seen. A peri-bronchial tuberculous affection is generally the cause of the phenomenon.

Such images have long been known to those who have made use of the Röntgen rays in the diagnosis of internal diseases, and their mechanism has been exhaustively explained in the "Atlas" by Holtzkecht that appeared in 1901, and which has never been improved upon.

Röntgenoscopy has shown that adhesions of the diaphragm take place, and that they may lead to considerable disturbance, even where no other morbid changes are present; that such adhesions may take place between the pleura pulmonaris and the pleura diaphragmatica, or between the parietal pericardium and the diaphragmatic portion of the pleura. When such images lie outside the pleural sinus, they are no longer to be detected by auscultation and percussion, as the respiratory sounds over the lower border of the lung are not altered by them, the respiratory gliding movement is not interfered with. At the most, atelectic sounds may occasionally be heard at the lower margin of the lung, and give rise to a suspicion that the lower part of the lung does not get a sufficient supply of air in consequence of diminished action of the diaphragm. The diagnosis, therefore, when it is made, can only be one of probability. Röntgen illumination, on the other hand, gives conclusions that are definite. It is true that the adhesions first become recognisable when they have reached a certain point, but with them the changes of the type of respiration, the irregularities, the indentations or scalloping of the diaphragm on inspiration, make the origin of the condition clear.

Of course, in making a Röntgenological diagnosis, the greatest caution must be exercised. The illumination must be made in various directions, and with the lamp at various heights, the patient always being kept at the same distance from the light. Covering shadows, that may be caused by projection of the

anterior or posterior ends of the ribs, must be excluded. Photographic apparatus should only be made use of when everything has been made clear. The picture should only be taken during the inspiratory pause.

Literary communications on the subject are very scarce.

Levy-Dorn and Zadek, as early as 1898, showed an illustration of a case of echinococcus of the lung, with distinct inspiratory kinking of the diaphragm. Benedikt showed an adhesion of the pericardium to the diaphragm by means of Röntgen illumination. Strauss showed a peculiar case of stenosis of the oesophagus that had become constricted by adhesion of the pleura. Stuert reported five cases of adhesions between the pericardium and the pleura, in which the diagnosis could only be placed on a firm basis by the Röntgen process. More recently Lehmann and Schmoll have described three cases of pericardial adhesion after injury, after pneumonia, and after polyarthritis.

Considering the dearth of communications on this subject, it will not be out of place to give a report of six other cases that have been met with during the last 3½ years in the I. Medical Klinik, in a total Röntgen material of 2,000 cases, and which have much in common with those that have already been published.

CASE 1.—This case resembles the case published 10 years ago by Levy-Dorn and Zadek in a remarkable manner. It also was a case of echinococcus of the lung. The patient was shown before the Charité physicians by Wadsack in 1906, but without anything remarkable being observed in the diaphragm. The case was shortly the following:—

A labourer, æt. 61, was admitted into the Charité in January, 1906, for hæmoptysis. The history showed that the patient had no hereditary tendency and, it was said, had never been ill before. On examination, independent of a few râles over the lungs, nothing was noted except a moderate arterio-sclerosis. Every day several bloody sputa were expectorated.

Frequent searches for T.B. were without result. On Röntgen illumination, a dark shadow the size of a five-shilling piece was seen on the left of the left margin of the heart, and separated from it, the meaning of which was not plain at first. Two months after admission, during which period no noticeable change had taken place, he was suddenly attacked with violent dyspnoea, with expectoration of red, frothy, thin sputum, in which some hooklets were found. As the expectoration abated, it was seen that the shadow was still present, but less pronounced and less distinct. It was then thought to be caused by the echinococcus.

In the summer of 1907 the patient was again admitted, as fresh hæmoptysis had taken place. Examination for T.B. gave the same negative result as before. The rounded shadow to the left of the heart was the same as before. No fragments of echinococcus were to be detected in the sputum.

The Röntgen image now showed on deeper inspiration, close to the heart, a rounded arching of the right arch of the diaphragm banded towards its upper border, an undoubted adhesion of the pulmonary pleura to the pleural diaphragm. As the echinococcus was on the left, and nothing was found wrong in the right lung, the meaning of the appearance was difficult to understand. At last we found that two years previously a board had fallen from a great height on to the right of the man's chest, that he had lain for weeks in great pain in the right side, especially on deep inspiration. It was plain that a pleuritis had been set up by the injury, with participation of the diaphragmatic pleura, that had led to adhesion. It was especially to be noted that the patient now no longer complained of much pain on deep inspiration.

CASE 2.—The patient was a medical man, who had no hereditary tendency to tuberculosis, and who had never suffered from any serious illness. In the winter of 1906-7 he had suffered for several weeks from a violent bronchial catarrh, which did not, however, compel him to lie up. He was examined several times, when it was decided that there was no serious affection of the lungs or pleura. During the period of the catarrh the patient had experienced violent pain about

the lower margin of the right lung. Recovery took place in January, 1907, but, even after this, on deep inspiration, an impulse to cough was felt with considerable dragging pain in the left side of the chest. The patient himself located it in the parasternal line of the sixth intercostal space, and described the pain as a disagreeable dragging or pulling. Examination of the powerfully built man in April, 1907, showed no morbid condition of the lungs, and it was especially noted that the mobility of the lower anterior border of the right lung was perfect. Both pulse and heart were equally normal. Illumination showed nothing essentially abnormal, either in the heart or lungs. In the pause the contour of the diaphragm was normal; on deeper inspiration, however, a slight scalloping was noticeable at the summit of the right half of the diaphragm. As I touched the corresponding part of the chest wall with the finger, the patient said, "Yes, the pain lies just behind there."

I made the following diagnosis: Circumscribed adhesion of the pleura pulmonalis to the pleura diaphragm; and prescribed a corresponding treatment consisting in gymnastic exercises and breathing under resistance. Some months later the patient wrote that under the treatment his troubles had gradually subsided, and that he could already perform some difficult gymnastic turns without any trouble.

From the Röntgen figure the diagnosis appears to me to be free from objection. The origin of the adhesion was brought about by a slight pleurisy coming on during the course of the catarrh. The diagnosis also appears to be confirmed *ex juvantibus*.

CASE 3.—The patient, æt. 25, had never been ill previously. In November, 1904, he fell whilst carrying a heavy sack upon some steps, and sustained some bruises on the chest and face; erysipelas followed, and traumatic pneumonia of the base of the left lung. In four weeks' time he was discharged from the hospital, but had to give up the attempt to work on account of a stabbing and dragging pain in the left side of the chest on any severe exertion. He was then sent back to the Charité for observation. The patient was an unusually powerfully built man. Examination of the heart and lungs showed nothing abnormal. Neither was there any change in the respiratory movements or in the breath sounds. Over the costal arch, in the anterior axillary line, there was said to be tenderness on pressure over a space of a hand-breadth.

Röntgen illumination showed a normal condition as regarded both heart and lungs. On the left leaflet of the diaphragm, even at the commencement of inspiration, but still more on deep inspiration, a sharp scalloping was noticeable, corresponding to the part where the patient complained of pain. The explanation of this adhesion lies in the history of the case. It was adjudged that the patient's working power was diminished by 25 per cent.

A year later he was sent to the Charité for renewed observation. He had gone back in the meantime to his old employment of sack porter, but always felt pain in the left breast on severe exertion, less, however, than formerly. On Röntgen illumination the scalloping was much less distinct than before; he was therefore pronounced fit for full work. It was evident that his work had done him good.

CASE 4.—Labourer, æt. 48, admitted May 24th, 1906.

The patient had never been ill. In December, 1901, he fell from a building a distance of 12 ft., sustaining contusions of the chest. After the accident there were signs of right pleurisy. The trade society at first gave him an allowance of 40 per cent. of his full pay; this was reduced after 18 months to 15 per cent., as no signs of the pleurisy were any longer present. The man, however, considered himself no longer fit for work on account of the persistence of the pain. For this reason he was sent to the Charité by the Reichsversicherungsamt for an opinion. On examination no changes were found in the bones of the chest. The circulatory apparatus showed moderate arterio-sclerosis. Over the lung, below and to the right, atelectatic sounds were heard, otherwise the lungs were perfectly normal.

On Röntgen illumination the following was seen. The lung fields were free, the hilus on both sides dis-

tinctly marked. At the heart the right arch pulsed upwards and to the right. In the resting pause the diaphragm showed moderate contours. On deepest inspiration, on the other hand, a semi-circular arching was seen close to the right corner of the diaphragm, which, measured auto-diagraphically, was 4.7 cm. broad, the greatest height being 0.7 cm. The arching was finely indented at its upper border. The condition was considered by myself as adhesion of the diaphragm that had led to considerable limitation of the power of movement of the right half of the part, and that had led to an atelectatic condition of parts of the lower border of the right lung. The situation of the adhesion corresponded to that in which the pain was complained of by the patient.

In my report to the Reichsversicherungsamt in regard to the determination of the amount of the diminution of the capacity for work on the part of the individual concerned, I was able to support my opinion by the photograph taken of the condition. In this case also Röntgen illumination had aided in procuring justice for a man who had received injury from an accident where auscultation, percussion, and palpation had failed to show that there was anything wrong.

CASE 5 was an out-patient, æt. 31. He had served ten years in the East African Guard Troops. During this period of service he had had repeated attacks of malaria, with implication of the liver, as was ascertained by several medical attendants. In later years he had complained of a feeling of pressure in the region of the liver. For about two years he had remarked that he could not breathe properly, and that on drawing a deep breath he felt a pulling, dragging pain in front under the costal arch in the parasternal line. Repeated examinations had revealed nothing, and he had been told that the pains were the remains of his inflammations of the liver.

The man had a washed-out look, but was fairly well nourished. The pulse was 80, and regular, but slightly quicker and smaller on deep inspiration. Nothing could be found wrong in either heart or lungs by percussion or auscultation. The liver projected a finger-breadth below the line of the ribs in the nipple line; the margin smooth, hard, and was somewhat tender on pressure. The spleen was palpable, and reached from the eighth to the ninth rib.

On illumination no changes were observed in either heart or lungs; the hilus was well marked. In the resting position both halves of the diaphragm were equally high, the leaflets equally rounded. On deep inspiration, however, the right half at the cardiac corner remained about three finger-breadths higher up than the other. At the same time a cord-like shadow, getting finer towards the side, was seen springing from the clear base of the right lung and attached just over the cardiac angle of the diaphragm. Here undoubtedly the figure originated in a pleuro-pericardial adhesion, and the atypical movement of the diaphragm in an adhesion connected with this between the pulmonary and the diaphragmatic pleura. Here also the parts that were adherent corresponded accurately with those in which the patient experienced difficulty.

Pleural adhesions had been looked upon here as the causal factor, this diagnosis having been arrived at by the process of exclusion, but only the Röntgen rays could make it certain.

The cause of these adhesions, as no acute disease of the heart or lungs appears in the history, must have lain in extension of inflammatory disease from the liver to the right diaphragmatic pleura, with extension to the pleura pulmonalis and the parietal pericardium.

CASE 6, æt. 59, a hide dresser, who for years had had to work in an atmosphere laden with dust, and for the last six or eight years had suffered from severe bronchial catarrh. For the last two years he had suffered also from difficulty of breathing, associated with a dragging, burning pain over the right costal arch.

The patient was somewhat emaciated, and examination showed considerable emphysema and advanced arterio-sclerosis. On examination by the usual methods nothing could be found in the liver or lungs to explain the troubles.

On illumination the usual signs of emphysema were found, as usually shown by radioscopy, great clearness of both lung fields, with wide intercostal spaces, nearly horizontal course of the ribs, depression and lessened movement of the diaphragm, signs of arterio-sclerosis of the heart, diminished shadow cast by the heart, towards the left, pulsation of the right upper arch, extension of the aortic band in the first oblique diameter.

On deeper inspiration a small, rounded bulging occurred, not quite sharp in its upper border, close to the diaphragm, which in orthographic projection corresponded exactly with the dragging, burning pain spoken of. Here also an adhesion between the diaphragmatic and pulmonary pleura appears to be established by the Röntgen rays. The explanation of the case is similar to that of No. 2, in which pleurisy with adhesions took place in the course of severe attacks of bronchitis, but which could not be determined by percussion and auscultation. The adhesion of the diaphragm is here, of course, only an interesting complication, which took the veil from the causes of an otherwise unexplainable pain.

CASE 7, a labourer, æt. 40, was a patient of the Poliklinik with struma, in whom, on Röntgen illumination, some changes of the cardiac shadow were thought to be present. The patient did not complain of any heart trouble. The usual examination, with the exception of acceleration of pulse, had revealed no changes in either the heart or lungs.

The X-ray examination also showed no changes, the normal contours of the diaphragm being present on medium inspiration, but, on very deep inspiration, a semi-circular bulging with an eaten-out appearance was seen immediately to the right of the cardio-diaphragmatic angle. The bulging was plainly seen in all directions of illumination, the most distinctly, however, in a mid-position between a dorso-ventral direction of the light and the first oblique diameter. A plate was taken in this position in the pause of respiration. The patient, on inquiry, then stated that some years before he had had an attack of right-sided pleurisy, that this had left nothing behind, but that frequently, on very deep inspiration, he had experienced a feeling of pressure in the lower part of the chest on the right side. A diagnosis of adhesion of the diaphragm without any other affection of the chest was free from all objection. As regards ætiology, the old pneumonia comes into question, in which it is very probable some pleurisy was mixed up, either of the pulmonary or diaphragmatic pleura.

I would sum up the results of the observations on the seven cases as follows:—(1) Röntgenoscopic examination of the chest is desirable in all affections of the thoracic organs. They become a necessity on diagnostic, therapeutical, and social grounds, when an ordinary examination fails to reveal the causes of the affection in question.

(2) Adhesions of the diaphragm can be demonstrated by the Röntgenoscope alone, when they lie outside the region of the pleura.

(3) Illumination is especially necessary when affections of the heart or lungs, or injuries to the chest, have preceded those that are the objects of inquiry.

## SOME REMARKS ON THE PERITONEUM AND PERITONITIS. (a)

By E. ROCK CARLING, M.B.LOND., B.S.,  
F.R.C.S.ENG.,

Dean of the Westminster Hospital Medical School; Assistant Surgeon, Westminster Hospital; Senior Assistant Surgeon, Seamen's Hospital, Greenwich.

ALL that is attempted in the present paper is the recapitulation of some of the established facts as to physiological processes in the peritoneum, and a cursory examination of modern methods for their practical application. If thereby, discussion is provoked, a good purpose will be accomplished. Surgical experience, in our early days, is partly derived from

(a) A Paper read before the Cork Medical and Surgical Society, October, 1909.

the individualities of our teachers, partly from the accumulated wisdom of tradition. But each of us acquires also, a growing mass of practical experience; we acquire it unconsciously, and have not always the leisure for extracting its full value by revision and sifting.

If when waiting to begin a laparotomy for "general peritonitis," we ask ourselves "Why am I going to open this abdomen?" The answer will probably be brief and to the point: "Because I know its right"; but the rational reply will have to be postponed to some such free moment as the present.

One of the most recent text-books of surgery in the German language, (1) begins its account of the treatment of peritonitis, under the heading "symptomatic," by recommending opium, and forbidding aperients. Of course, the authors go on to describe the great reduction of mortality effected by early surgical intervention; but still, *there stands* "masterly inactivity," as a possible attitude for a modern surgeon towards peritonitis.

Why is it not our attitude? Why do we open the abdomen at the earliest possible moment in every case of acute peritonitis?

The superficial area of the peritoneum is scarcely less than the whole skin surface of the body. It is no surprise to us that the quantitative toxæmia of even a mild infection, affecting a large area of the body—say, in a case of extensive scalding, or in pityriasis rubra—should be a very grave and serious matter.

It is surprising on the other hand that widespread infection of the peritoneum—a tissue which does not share the advantage of the skin in shedding a large part of its discharges outside the body—should not be even more rapidly, and certainly fatal.

We know with what extreme rapidity foreign particles find their way from the cœlomic cavity into the lymphatic, and even into the hæmic, circulation. Blood corpuscles left free in the peritoneal cavity of a dog reach the lymphatics and anterior mediastinal glands in less than an hour. (2) Five minutes after the injection of a large dose of typhoid bacilli into the peritoneal cavity of guinea-pigs or rabbits, the organisms can be recovered from the blood drawn from the ear. (3) Iodine can be found in the urine of guinea-pigs fifteen minutes after its introduction into the peritoneum. (4) Rice-flour particles can be recovered in blood from the pinna one hour after its injection into the peritoneum; (5) inert particles have been found in the spleen fifteen minutes, (6) and in great numbers, two to four hours after introduction. The old idea of the peritoneum as a huge lymphatic space, communicating directly with the lymphatic circulation by "stomata" and "stigmata," the descriptions and figures of which were familiar to us as students (7)—has been exploded by more recent work. (8) (9) It is now generally recognised that all particulate and a great deal of the fluid absorption from the peritoneal cavity takes place *via* the diaphragmatic lymphatics, but Wegner's (10) observations on absorption through the lymphatics of the meso-rectum, gastro-hepatic, and other omenta—have not been specifically disproved. Indeed, carmine, whilst chiefly finding its way through the diaphragm, diffusely stains the parietes. Actinomyces, injected into the cavity, are found studded thickly over the diaphragm, whilst a few occur in the pelvis, none in the walls, but plenty in the mesentery.

MacCallum (2) has described cilia on the endothelial cells, but he ascribes a very important *role* to mechanical aspiration by the diaphragm, in determining the flow of fluid, and movement of solid, particles towards the upper part of the abdomen; and to the rhythmical contractions of its interlacing muscular fibres in promoting their passage into the lymphatic circulation through the tenuous endothelial covering of the lymphatic lacunæ and spaces, lodged between them.

One hour suffices for leucocytic reaction in an irritated peritoneum; thenceforward the vast majority of absorption of solid particles takes place after

phagocytosis; bacteria, blood cells, and inert particles, such as carmine, are all engulfed, enter the lymphatic stream and reach the mediastinal lymph-glands, or find their way *via* the thoracic duct into the blood stream.

There is, however, one very important factor which the work of Durham, (11) and more recently that of Buxton and Torrey, (12) have demonstrated, and which operative observations suggest, viz., that the great omentum may act as a most efficient filter, as a natural inhibitor of the usual trend of bacteria towards the diaphragm, where immediate transference to the circulation would be their fate. Durham speaks of the omentum as *par excellence* the seat of election for removal of leucocytes from the peritoneum during infection. Others (19), (20), (21) also have demonstrated its protective *role*, and some even consider it the main path of absorption. (13) The peritoneal fluid may be sterile, and yet the omentum contain bacteria. Here I may mention a most interesting observation of Buxton's, (6) that the sera of immunised animals are not more bacteriolytic, but that leucocytosis is, in them, much greater, than in control animals. Fluids are probably absorbed from the cœlum both by the lymphatics and veins, and the rate may be remarkable. A dog can absorb from its peritoneal cavity in one hour, an amount of blood-serum equal to one per cent. or even eight per cent. of its body weight. (14) Absorption is dependent on the pressure exerted by the abdominal muscles—not only their normal "tone," but also their rhythmical respiratory contractions; upon the pump-like action of the diaphragm; upon peristalsis, in so far as it opposes the action of gravity upon the free contents of the sac; and lastly upon the vitality of the endothelium.

Some writers have thought it impossible to increase the rate or amount of absorption usual in physiological conditions, but it is now fairly certain that the rate and amount are both increased (4) in the early stages of infection. Diminution in the amount may be produced by chill, (15) (16) which inhibits peristalsis and contracts the blood-vessels. Heat applied externally also has the same effect, (17) probably for similar reasons. Drying (18) too, leads to diminution. For protection against infection from the peritoneum there is almost entire dependence on phagocytic action. The peritoneal fluid may possess bactericidal properties, which are indeed sometimes capable of "explosive action" (3) in the immediate destruction of bacteria. Whilst there is often an initial leucopenia, it is quickly followed by a leucocytosis. The white cells invade the peritoneum in enormous numbers and become very actively phagocytic in a few hours. There is a good deal of difference of opinion as to the source of the phagocytes and as to the exact character of those evincing the highest engulfing properties; the truth being that for different organisms, and at different stages of the process of infection, different orders of leucocyte, and even of endothelial and connective tissue cell, are most potent.

We may take it that bacteria which survive the immediate lethal action of the peritoneal fluid are taken up by leucocytes and transported *via* the diaphragm to the lymph glands, the blood stream and the tissues, there to undergo bacteriolysis; others, meshed in the fine film of fibrin, with which we are familiar as dulling the normally shiny surface of the peritoneum, or actually affording a visible coating of lymph, are bound thereby to the great omentum, which is quickly crammed to distension with actively phagocytic leucocytes; by their agency the micro-organisms are transferred to the efferent lymph channels.

(22), (23) Many methods have been proposed and practised to promote leucocytosis. Mickulicz injected nucleinic acid; Chantemesse and Kahn used a prophylactic injection of sodium nucleinate, Borchardt and Schmidt used horse-serum; simple NaCl, is credited with similar properties by many surgeons. It appears from the work of Dudgeon and Sargent that in many cases of peritonitis, rapid mobilisation of defensive

phagocytes is effected by the agency of an innocuous but fortunately almost ubiquitous, organism, the *staphylococcus albus*; this organism which is probably an inhabitant of the intestine, given law enough, will prepare an adequate defence against almost any invasion however virulent. Preliminary injection of this organism will afford protection against a virulent culture of the colon bacillus injected twenty-four hours later. Unfortunately, it is not enough that, given time, the leucocytes will probably succeed in removing all bacteria from the peritoneal cavity. Often they are not "given time." Absorption of bacterial toxins takes place sometimes with all the rapidity indicated above for experimental observations. Before certain strains of *Streptococcus*, and sometimes before the *B. pyocyaneus*, the leucocytes are powerless. The toxins have been shown to exert a special deleterious action on the bulb, and thence on the cardio-vascular system, more particularly in the splanchnic area, plethora of which leads to cessation or diminution of fluid absorption by the ordinary route. If, however, under these circumstances the endothelial cells are devitalised or shed, or mechanically removed, direct absorption into the subserous vessels is permitted, and may proceed with fearful rapidity. Thus even the temporary gain from stasis is neutralised.

The extraordinary complex conditions controlling osmosis and dialysis (24) are easily and too often disturbed in some fashion adverse to the organism as a whole, with reference to these poisons. One action of the toxins is to paralyse the plexus of Auerbach (25) in the intestinal wall, the muscular tissues of which are already handicapped by oedema and venous congestion; in consequence, peristalsis fails. That very "plastic exudate" which is the second line of defence in all cases of local infection of the peritoneal cavity, by agglutination of adjacent structures and isolation of the infective focus, serves to hinder peristalsis still further. This, by inhibiting intestinal movements, may stay the spread of infection, but it permits stagnation of the contents of the gut, and that in itself constitutes a grave danger. We can guess at the meaning of this danger when we think of Starling's experiments on the elaborate chemico-nervous mechanism controlling gastro-intestinal digestion, and the disasters that follow upon its derangement.

With comparatively few exceptions, clinical indications of the nature of the infecting organisms are not available at the time of operation. (26) Some authors (27), (28) have thought they could distinguish a streptococcal from a coli infection; others deny the possibility. One (29) thinks a streptococcal peritonitis is generally without distension; another (30) thinks distension of the abdomen the "most important diagnostic sign of peritonitis." These are the vague terms used by those who seek to correlate clinical indications with bacteriological findings. Even the appearances met with within the abdomen are not an absolute guide. When a child's abdomen is found full of buttery pus, or of material like "beef-tea," (31) one may suspect the presence of the pneumococcus, but whether or not it is present in pure culture is quite uncertain. The pronounced odour with which we are so familiar in cases of appendix abscess, may indicate the presence of *b. coli*, but it does not exclude the staphylococcus or even the dire *b. aerogenes capsulatus*; the elusive anaerobic organisms whose toxins are accused of such intense virulence, give no unmistakable sign of their presence. The locality of the source of infection, does afford some hint as to the probabilities of finding, or not finding, certain organisms; it is little more than a hint.

When the peritonitis is due to perforation of the stomach or duodenum, the infecting organisms are very often of low pathogenicity. Towards the lower end of the small intestine and in the large, the organisms liberated by perforation, or permitted to reach the peritoneum through macroscopically intact walls—a possibility well-established (33), (34), (35)—may be of very varying virulence; different combinations of organisms, as, for example, the association of streptococci with colon bacilli, or differences in the strain due

to intra-intestinal conditions, may account for any degree of menace from a mild irritation up to an invasion too violent for the normal process of defence to withstand unaided and too sudden for the assistance of art to be invoked. Infection reaching the peritoneum from the female generative organs is often of low virulence, sometimes the gonococcus is alone concerned, or it is associated with other organisms, or it is outrun by them before the serosa is reached. On the other hand the peritonitis of puerperal fever is perhaps as virulent as any infection ever seen. From perforation of a gall-bladder the anticipations simulate those from perforation of gut somewhat lower than the opening of the bile duct in the duodenum. Infection from without, as by stab-wound, or by injury in instrumental efforts to procure abortion, or during operative measures, may vary in virulence, just as with infected wounds elsewhere.

Even shed blood in the peritoneum does not, as Dudgeon and Sargent have shown, remain sterile. The *Staphylococcus albus*, generally the surgeon's friend, may strain the compact by its demands. The different modes of origin, the different infective agencies, the different stages of the disease at which intervention becomes possible, the different conditions actually found, all demand appropriate treatment. The only law applicable is an injunction to avoid all golden rules.

Certain points then, it seems to me, are worth keeping in mind clearly.

The amount of peritoneal fluid normally present is minimal. It is supplied in the main by transudation from the great omentum, and is constantly aspirated towards the dome of the diaphragm where it passes through the endothelial membrane into the lymphatic spaces and channels back to the circulation. The amount of this fluid is considerably increased in the presence of an infective agent, and moreover its cellular phagocytic content is raised to an enormous extent. This cellular increase is purely protective; it is due, partly to proliferation of the endothelium itself, but mainly to the white blood corpuscles. During the initial stage of increased fluid exudation, there may be a leucopenia. (11), (32) All cells save the lymphocyte are balled and clumped and become adherent to the peritoneal surface, chiefly of the omentum. Phagocytosis is active except in the presence of organisms of high virulence. An hour later the polymorphonuclear leucocytes appear on the scene, and their numbers increase for fifteen hours or so, the fluid becoming turbid in consequence. The polymorphonuclear cells, after active phagocytosis, are themselves ingested by macrophages of endothelial origin. In some cases death may ensue without, to all appearance, more than slight changes in the peritoneum, the "collapse" to which the fatal result is attributed being no more than the expression of an intense toxæmia, which the defensive processes have been powerless to inhibit.

Denudation of the tissues underlying the serosa, affords a nidus for the unhindered development of bacteria. Again, virulent substances are produced as bye-products in the process of normal digestion; the body is normally protected against them, at any rate in part, by the activity of the bacterial inhabitants of the alimentary tract. When peristalsis is impaired or abolished, when the walls of the gut are congested, and infiltrated, when the conditions permit multiplication of the contained organisms, and increase of their virulence, it is to be expected that toxic substances will be produced in quantity and quality exceeding the normal, whilst only a partial compensation can be expected from concomitant decreased activity of the normal channels of absorption.

Every surgeon is familiar with the heart-sinking he experiences in seeing his patient begin to vomit the foul brownish-black, grumous fluid which regurgitates in late stages from the intestines to the stomach.

#### TREATMENT.

The object of treatment should be:—

- (1) To intervene at the earliest possible moment, with the object
- (2) of removing the source of infection,
- (3) to damage and disturb the peritoneum as little as possible in doing this,
- (4) to remove as few as possible of the still-active phagocytic cells,
- (5) to divert the peritoneal current from its usual course to the diaphragm, towards the exterior through appropriate apertures, as long as active fabrication of toxins and multiplication of organisms are proceeding,
- (6) to fill the peripheral vessels, in compensation for splanchnic stasis; to dilute the toxic contents of the blood and promote excretion by the kidneys and thereby elimination of toxins and even of bacteria;
- (7) to promote evacuation of the intestinal contents. This may be of greater importance, in view of their highly noxious character, than the avoidance of further spread of the infective agent by peristalsis; indeed, it is chiefly requisite when the peritonitis is already diffuse or general;
- (8) To put confidence in the extraordinary defensive scavenging and recuperative powers of the peritoneum, when it is given a chance.

Not all these recommendations can be put into practice simultaneously, nor is it essential they should be; some are definitely conflicting, and the indications for selection must be matter for each individual case, for experience and for prompt judgment, too often upon inadequate data.

Where the peritonitis is diagnosable only vaguely as "peritonitis" every surgeon operates. As an adherent of early operation, I extend my opinion to include those local, or localised infections the source of which can be recognised with reasonable assurance. Without denying, for a moment, that circumstances may make immediate operation inexpedient, I regard those circumstances as to be deplored. I have never had to regret early operation: I confess, with sorrow, I have too often had to lament hesitation and delay.

With regard to damaging the peritoneum, one is often in a cleft stick. Not only must it be remembered that to detach the film of leucocytes, fibrin, and proliferating endothelial cells, is to make a breach in the continuity of the natural defences, but also, that we increase thereby the menace of subsequent adhesion; adhesion which may result either in acute angulation or in chronic fibrous junction. When, owing to the difficulty in finding or reaching the source of infection, or owing to difficulties with the anæsthetic making relaxation impossible, or owing to imperfect assistance, the small intestine is allowed to escape, its reposition may be a matter of great difficulty, necessitating very firm handling. This may easily lead, especially in the case of children, to hæmorrhages into the walls, and worst of all to splitting of the peritoneal coat along a whole loop—a disaster quite serious enough to rob the patient of the small chance already remaining. It is extremely difficult to suture such splits in the serous coat, with accuracy, even after letting the contained gas out of the affected loop, the tissues being too soft and infiltrated to hold the silk.

To let out from the lumen a big \*dose of bacillus coli into a peritoneal sac, already taxed to its uttermost in dealing with another infection, is equivalent to a death sentence.†

## OPERATING THEATRES.

### MIDDLESEX HOSPITAL

WHEELHOUSE'S OPERATION FOR STRICTURE.—MR. JOHN MURRAY operated on a man, æt. 42, who had been admitted four days previously suffering from stricture of the urethra complicated by retention of urine. The patient stated that he had had an attack of gonorrhœa twelve years previously, which had lasted a week. He had had no further trouble until twelve months ago, when he began to have difficulty in passing water, and he noticed that he passed it in a smaller stream than usual. Six months ago he found that his urine began to dribble away constantly, and this condition had continued ever since. He came up to the out-patient department about six weeks before. An unsuccessful attempt was made to pass an instrument into the bladder, and the patient was then advised to come into the hospital. From the date of his attendance in the out-patient department up to the time of his admission he had never been able to pass his urine in a normal manner, but it had been constantly dribbling away. On admission, the bladder was distended, and reached just below the umbilicus. An attempt was made to pass various instruments, including a small silver catheter and a filiform bougie, but without success. As the patient was not in any pain, and there was no indication for giving immediate relief to the retention, which had evidently existed for the last six or eight weeks, the patient was ordered a purgative and a hot bath night and morning. Three days later another attempt was made to pass an instrument through the stricture, but this also failed. It was therefore decided to operate. When the patient was under the anæsthetic a final attempt was made to pass a catheter, but this being unsuccessful, the man was placed in the lithotomy position and a Wheelhouse's staff passed down to the stricture. A median perineal incision was made, and the urethra opened on the staff. On separating the edges of the divided urethra, the proximal opening was easily found, and about half-an-inch lower down the urethra was almost occluded by a dense annular stricture. Wheelhouse's probe pointed director having been inserted, the stricture was divided and a gorget introduced into the bladder, when a large quantity (about 20 oz.) of clear normal urine escaped. A full-sized gum elastic catheter was introduced through the meatus and passed into the bladder. It was then tied in, the perineal incision was closed over the catheter by silkworm-gut sutures passed deeply into the corpus spongiosum, and the wound dressed.

Mr. Murray commented on the fact that cases of stricture admitted as in patients appeared to be of much less frequent occurrence now than formerly, and the complicated cases of stricture, such as cases of extravasation of urine and strictures associated with perineal fistulæ were of infrequent occurrence. He was of opinion that this was due to more efficient

treatment of gonorrhœa and to the improvements in the methods of treating stricture, more especially with regard to the sterilisation of all instruments used for the purpose of dilating the stricture. The case under consideration called for treatment on account of two conditions—namely, retention of urine and a stricture. With regard to the retention of urine, considering that it had continued certainly for two months, that the patient was not in pain, no immediate relief was necessary. When he first saw the man he hoped that the treatment adopted—namely, rest in bed, hot bath night and morning, and saline aperients—would cause sufficient relief of muscular spasm to enable an instrument to be passed. He pointed out that cases of stricture complicated by retention are usually associated with spasm of the urethral muscles, and that where it is impossible to introduce an instrument when the patient is first admitted, after a few days one can be introduced without any difficulty, and this line of treatment should, where possible, be adopted. With regard to the choice of operation, there could be no doubt, he thought, that Wheelhouse's operation was the one indicated as affording relief to the retention and stricture at the same time. With reference to the operation, there were two points which struck him as interesting. One was in regard to the stricture: although it was very tight, it was circumscribed, the urethra, except at one point, presenting a normal appearance; the other was the fact that the urine which was drawn off was perfectly clear and showed no sign whatever of decomposition or evidence of cystitis, which, he thought, still further goes to show that such complications are caused by the passage of imperfectly sterilised instruments, and not by infection along the urethra. He said that the difficult part of Wheelhouse's operation often was finding the proximal end of the urethra; in this case no such difficulty was experienced, partly because the stricture was localised and the urethra healthy in the rest of its course. With regard to closure of the wound, he thought this was one of the important points in the obtaining a satisfactory result. The ideal method would be to suture the urethra over the catheter with buried sutures, but the danger of slight septic infection and subsequent trouble from the buried sutures was a great objection to adopting this method. He had tried it on several occasions, but had abandoned it. In this case the wound was closed completely by silkworm-gut sutures passed deeply, and he was led to adopt this course because of the apparent absence of any septic infection of the urethra, and he hoped by this means to obtain primary union, as he had obtained in several previous cases. Where there was obviously septic infection present, and especially where the bladder had become infected, he advised leaving the perineal wound partly open, closing the upper and lower extremities of the wound with silkworm-gut sutures, and packing the centre with sterilised gauze.

He said that if all went well the catheter would be left in for ten days and then withdrawn, after which a silver catheter would be passed every second or third day. When the patient leaves the hospital he will be advised to attend the out-patient department at first once a week to have an instrument passed.

## TRANSACTIONS OF SOCIETIES.

### ROYAL SOCIETY OF MEDICINE.

#### SECTION OF THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD NOVEMBER 26TH, 1909.

Dr. PORTER PARKINSON in the Chair.

Dr. A. E. GARROD showed a case of multiple peripheral neuritis in a child, æt. 8. The child was quite healthy until March, 1909, when she passed involuntarily a stool containing several ounces of blood. This was preceded by an attack of abdominal pain. A similar attack occurred in May, and several others later. When admitted to hospital on September 16th,

she was a well-nourished child; good mental condition; marked loss of power in both upper limbs from deltoid downwards, and double wrist-drop; muscles of lower limbs weak; no tremor; sensation unimpaired; other systems normal. Electrical reaction showed muscles of all extremities with reaction of degeneration (except flexors and special muscles of thumb and little finger). Blood examination: red corpuscles, 4,984,000; hæmoglobin, 94 per cent.; white cells, 10,500. No cause for the condition was discoverable.

Dr. G. A. SUTHERLAND regarded the case as one of special interest, and thought a certain positive diagnosis was not possible.

Dr. E. I. SPRIGGS referred to two similar cases shown at the last meeting.

Dr. ROBERT HUTCHISON showed two cases, one a female child, æt. 9, with cirrhosis of the liver. There had been swelling of the abdomen for one year; no previous illness of importance. Two still-births preceded this child. There were snuffles as a baby. The liver was enlarged and irregular, and the spleen considerably enlarged; some ascites; the child had a cirrhotic facies. Dr. Hutchison took the view that the condition was due to syphilis, and stated that a positive vasomen reaction had been obtained.

The other case was one of unicdactyly in a male, aged 13 weeks. The small digit only was present on both hands and both feet. The child was otherwise normal. The child's father, two uncles, and an aunt are similarly affected, as also the grandfather and his brother. A daughter of the father's sister also exhibits the condition.

The Chairman, Dr. Shuttleworth, Dr. Chapman, Dr. Sutherland, and Dr. Garrod discussed the cases.

Mr. O. L. ADDISON showed a case of congenital enlargement of one limb occurring in brother and sister, æt. 9 and 5 respectively. The boy's arm, shoulder, and hand were enlarged, and there was one inch increase in length.

In the girl the enlargement was in the left leg, which was an inch and three-quarters increased in length. The calf was relatively larger than the thigh, and was hotter than the rest of the limb.

The cases were discussed by Dr. Parkes Weber, Mr. Mummery, and Dr. Garrod.

Dr. R. C. JEWSEBURY exhibited a specimen of an infantile heart showing nodules on the endocardium. The specimen was from a child, aged 4 months, who died from broncho-pneumonia. No cardiac lesion was detected during life. Post-mortem, a large number of wart-like nodules were found, especially on the mitral and aortic valves, a few also on the other valves, and on the septum of the foramen ovale. Microscopical sections through the nodules showed a connective tissue substratum supporting a layer of epithelium. There were no signs of recent or previous inflammation. There was nothing to suggest that the nodules were "vegetations," and it was stated that the condition occurs normally in the infant heart.

Dr. SPRIGGS regarded the nodules as hypertrophy of the little nodules usually seen in infants' hearts.

Dr. ROLLESTON, for Dr. Carpenter, exhibited a specimen of compression of the trachea by the enlarged thymus. The specimen was removed from a child, 10 months old, who died after an illness of less than 24 hours, which began suddenly with quick breathing and sickness. The temperature reached 103°, and the respiration rate was 80. During life there was recession of the intercostal spaces and embarrassed breathing. The specimen showed a large thymus pressing on the trachea, which was much narrowed from before backwards. The lungs showed evidence of death from asphyxia. The liver and spleen showed some fatty change, but the other organs were normal. The case was shown as positive evidence that an enlarged thymus may cause death.

He also showed a microscopical section from the liver of a case of icterus in an infant. The specimen showed a normal condition of the liver.

Mr. LOCKHART MUMMERY read a paper on a case of STRANGULATION OF THE SMALL INTESTINE by a band in a child, aged 15 months. The child had acute obstruction, which developed suddenly, and was

operated upon within 9 hours of the onset of symptoms. A tumour which was thought to be an intussusception was distinctly felt in the right side of the abdomen. The child had been operated upon for intussusception when 5 months old. On opening the abdomen a loop of small bowel was found acutely strangulated by a narrow band. The band was divided, and the abdomen closed. The child made an uninterrupted recovery.

# ROYAL ACADEMY OF MEDICINE IN IRELAND.

## SECTION OF SURGERY.

MEETING HELD FRIDAY, NOVEMBER 19TH, 1909.

The President, J. LENTAGNE, P.R.C.S.I., in the Chair.

THE PRESIDENT said that last year, in opening the session of the Section, he had spoken of the "present position and future prospects of the Academy," and had then been compelled to draw a rather gloomy and depressing picture. He had had to deplore the indolence and apathy which, in his opinion, were steadily destroying the life of the Academy. He thought he could not do better, in opening the present session, than return to the subject. Looking back over the work done during the past session, he was sorry he could see no evidence of improvement in respect of attendance. The number of total attendances at the six meetings of the Section had been 152, or an average of about 25 at each meeting, as compared with 167, or an average of about 28 the previous session. An analysis of the attendances showed that the Fellows had been a little more attentive in the past session, but it was a curious thing that no attendances were recorded by students, as against 21 in the previous year. He was, however, glad to say that the record of work done was a much more cheerful one. During the past session they had had many valuable papers, and many cases of extreme interest had been exhibited, which made him all the more surprised that the attendances had been so small. He considered that the record of papers and exhibits brought forward was one of which any Society like theirs might well be proud, but small, in view of the fact that there were over seventy men in Dublin engaged in the teaching and practice of surgery, as well as hundreds of students to whom the meetings of the section should be of great importance. He asked those present to assist in improving this state of affairs.

### OPERATIVE TREATMENT OF FRACTURE.

Mr. R. LANE JOYNT read a paper on above. He pointed out the result of X-ray examination of united fractures of the femur which had been treated by the common methods showed in many cases an amount of deformity which was little short of that seen in a number of museum specimens which were formerly regarded as examples of mal-union. The functional result in most of these cases was very bad. The only way in which shortening could be prevented, and the fragments got into perfect line, was by operation. Even when complete asepsis was not obtained, suppuration was usually slight, and the results were much better than when the older methods were employed. A striking feature after the fixation of the fragments was the rapid disappearance of pain. He then described minutely the details of the operation for wiring, and of that in which Lane's steel plates are used. He showed a number of instruments which he had found very useful in carrying out these operations.

### OPERATIVE TREATMENT OF FRACTURE, ILLUSTRATED BY X-RAY PHOTOGRAPHS.

Mr. W. I. DE C. WHEELER read a paper on above, and showed four cases where simple treatment had failed, but continuity and union was afterwards established by the use of screws and metal plates. In one case the operation was performed 3½ months after a compound fracture of the tibia and fibula, which failed to unite, and rendered the limb useless. After operation complete union was obtained, the wound, which was partially open, healing, over six screws holding two plates. The fibula was wired. A second case pre-

sented himself for treatment (11 months after the accident) for a false joint of the tibia and an ununited fibula following simple fracture. Firm union was obtained after excision of the joint, and the introduction of screws, wire and plates. The third case was that of the surgical neck of the humerus, with a marked tilt outwards of the upper fragment; the upper end of the lower fragment was embedded in the muscles under the coracoid process. A fortnight's treatment under the guidance of X-rays failed to reduce the deformity. A single plate supported by an encircling wire was introduced to hold the fragments in position. The last case was that of a child, æt. 4, who sustained a long spiral oblique fracture of the femur. Extension under an anæsthetic and immobilisation of the fracture in plaster-of-Paris failed to reduce the overlapping of the bones. Finally, operation was performed, and two plates and three encircling wires introduced. All the wounds healed by first intention.

THE PRESIDENT of the Academy said they had had from Mr. Lane Joynt one of the best demonstrations he had ever seen of the application of practical mechanics to surgery, and he thought it a pity that there were not means of teaching something of the subject to medical students. What had struck him most about the instruments shown was their size and business-like capability. The majority of instruments used for bone surgery were small and incapable. He had often speculated as to how the long American spindle turn-screw could take out a screw that could not be touched with a short one, and until that night he had never heard anything like a reasonable explanation.

Sir THOMAS MYLES recalled the fact that he had in 1884 brought forward a suggestion for the operative treatment of fractures. A quarter of a century had passed since then, and thirty years since the introduction of antiseptic surgery, and yet it was only to-day that the operative treatment of fractures was becoming general. They had taken a long time to get out of the routine methods of procedure. Mr. Joynt had shown them that, even when suppuration ensued, if proper provision was made for drainage, the results of operative treatment were infinitely better than those of non-operative treatment, no matter how well carried out. It was hardly yet time to dogmatise as to which of the operative methods was the best. Most of them had tried the three methods—the method of wiring, the method of the Lane plates, and the Parkhill method, which was capable of being used in many cases with less disturbance than the method discussed that night. The particular advantage of any operative method was not shown so much in fracture of the middle of the shaft of the femur as in fractures in the neighbourhood of the joints. He had had five cases of recent fracture under his care. In the case of a man of fine physique who declined to be operated on, and for whom he did everything to make the non-operative treatment a success, the result was a shortening of 1½ inches, and the patient had not recovered the functional use of the knee-joint. In another case of fracture and dislocation of the head of the humerus, the bone was got back into the socket after tremendous difficulty, and anyone could recognise that nothing but bold operative treatment could possibly have given the man a limb of the least use. After two years the patient had a little stiffness in the shoulder. Comparing the results in operative and non-operative treatment, he did not think anyone would hesitate in advising the operative.

Mr. MAUNSELL cited cases in which he had got good results by wiring, but with great difficulty, whereas when he had used screws and plates in identical cases the operation was not at all a hard one. In a case of compound fracture the plate had come away about five weeks after the operation, but it had not interfered with the result. He did not, however, think that wire had been outdone by screws. Operative treatment was not required in every case, as even in the femur he had got good results with plaster, especially in young people, which he did not think could be improved on by operation. He thought it would be unfair to rush into operation before trying other methods. Cases

such as those mentioned by Sir Thomas Myles might have to be operated on from the first, but he had had recently two cases of fractured femurs, both of which had gone out after treatment with no shortening.

Mr. HAUGHTON said those surgeons who viewed the conditions of fracture through X-ray examination became more and more convinced of the necessity for an improved method of treatment. He held personally that it was even more important to take an X-ray picture after the application of splints than before they had been applied. If the position was not satisfactory they could then proceed to operative treatment. He used a small screw-driver on small bones for fear of splitting, but the long screw-driver was more convenient.

The PRESIDENT said he had been speculating as to how he would treat the case of fracture of the lower end of the femur just above the knee-joint in which they might have one of the fragments presenting backwards toward the skin of the popliteal space. He would like to know what incision Mr. Lane Joynt would propose to make for such a fracture, or in separation of the epiphysis in that situation. He remembered two cases of the kind which had been treated by distinguished surgeons, and the results had been lamentable. He himself believed that a good deal could be done by posture. He had treated cases by keeping the leg bent to a right angle, but the position was extremely irksome, and the results, though very much better than former ones, were not to be compared with what they could now get by suturing or plating. If they were to operate at all in a case of fracture, the sooner it was done the better; delay added to the difficulty of the operation and interfered with the beneficial result. He had found the Parkhill clamp difficult to employ; it left several holes in the skin, and there was always greater danger of sepsis. The greatest danger of sepsis was not during the operation, but during the first week or two after the operation.

Mr. LANE JOYNT, in reply, said that in approaching the knee for a fracture in the lower third, they would have to go from the outer side, and probably apply a plate. It was easier to work from the outer side than from the inner, and he thought also that they would be able so to avoid the capsule of the joint and the prolongation of the synovial membrane. He would not, however, object to opening the joint, as it could be done without necessarily destroying it. If they were going to place a plate on the bone in the neighbourhood of the joint, it should be, if possible, not in a place exposed to friction. He would not use wire there, no matter how tempting it might look. As regards Parkhill's method, he looked upon it as being superseded in some cases; but there were others, notably where they might have a compound fracture of the tibia with excessive suppuration and necrosed bone, in which it would be folly to attempt to suture or screw with Lane's plates, or wire. Wire was not outdone by any means. There were times, as when dealing with fractures in young children, when they should use fine wire. In such cases the shortening would be the same, when the patient was fully grown, as in childhood.

Mr. WHEELER also replied.

#### HARVEIAN SOCIETY OF LONDON.

MEETING HELD NOVEMBER 15TH, 1909.

The President, Dr. CHARLES BUTTAR, in the Chair.

Dr. ALEXANDER MORISON read a paper on the NATURE AND TREATMENT OF ANGINA PECTORIS.

He remarked that if the terms were used comprehensively as applying to all forms of cardiac pain, the condition was not rare, but if limited to classical cases, mostly without valvular disease, we could understand the fact mentioned by Stokes, of Dublin, that he had never seen a case. Dr. Morison, however, would treat the condition more comprehensively, and defined angina pectoris as a painful affection of the heart as a whole, dependent upon disorganisation in

the anatomical character or disorder in the physiological function of one or more of the factors in cardiac action, and associated in some cases with a fear of impending death. He gave a short abstract of the cases as supplying the data upon which he rested his conclusions regarding the nature of the affection, instancing cases both of dextral and sinistral radiation of the pain. The conclusion he arrived at was that the character and situation of the conditions which originate angina vary, and that the heart is, like other viscera, endowed with low sensibility to handling and other modes of external irritation under normal circumstances, may in the presence of lesion of its internal surfaces, or severe stimulation of its nervous endowment by compression or otherwise, reveal evidences of sensibility as well marked as do other viscera in their interior under circumstances which may be regarded as analogous. He argued that even the commencement of referred pain in a peripheral portion such as the arm in no way invalidated the belief that intra-aortic or intra-cardial nerves were not also the seat and site of referred pain.

In speaking of treatment, he divided his remarks into a consideration of the treatment (1) of the attacks, (2) of the conditions which provoked the attack, and pointed out that the majority of cases of so-called vasomotor angina with valvular disease tended to subside without accident so far as the attack was concerned. This was not so with non-valvular cases, which might rapidly terminate fatally, and required, not merely the use of nitrites, but also of morphia, atropin and general anaesthesia for relief and to arrest death. At the close of his remarks Dr. Morison showed a patient upon whom thoracotomy had been performed with benefit for cardiac pain, and an account of whose case has already appeared in the *Lancet* for July 4th, 1908, and November 20th, 1909.

In the discussion that followed:—

Sir THOMAS CLIFFORD ALLBUTT said that, to properly understand the nature of angina pectoris, it was necessary to consider cases that were not complicated. He considered that the cause of uncomplicated cases of angina pectoris was disease of the aorta above the valves, and he thought that the distribution of the radiating pain depended largely on the part of the aorta affected. He thought that there was a pain arising from the heart itself, and situated in the præcordial area, which was quite distinct in character from the pain of a typical angina attack. He insisted on the importance of early specific treatment in cases of angina pectoris.

Sir RICHARD DOUGLAS POWELL considered that cases of typical angina pectoris were due to atheroma and thrombosis of the coronary arteries. He would not class as angina mere aortic pain following exertion. He considered rise of arterial blood pressure an important factor in the causation of angina pectoris, and gave instances of cases in which the development of mitral regurgitation had caused relief from anginal attacks.

Sir THOMAS LAUDER BRUNTON thought that the pain of angina pectoris was partly due to contraction, and he compared the pain to the contraction of a distended bladder. He considered that there was an elusory nerve supply to the heart, and cited the results of experiments on animals in support of this. He thought that the pain of angina pectoris was due in some cases to increase of arterial blood pressure; in other cases spasm of the coronary arteries was an important factor. He laid stress on the importance of careful regulation of exercise in angina pectoris, and also on the advisability of rest after a meal.

Dr. JAMES MACKENZIE thought that the symptoms of angina pectoris should be carefully understood, and that the distribution of the pain should be carefully investigated. He thought that irregularities of the heart were important, and also that great exhaustion of the heart muscle was usually present in angina attacks.

Dr. LEES said that many of the attacks of so-called angina pectoris were not really typical. He thought that a very important confirmatory physical sign was a dilated aorta, and emphasised the importance of a careful examination by percussion. He considered that excessive indulgence in tobacco smoking was a

very important factor in the causation of angina pectoris. He said that investigation of the nerve plexuses about the aorta was very necessary before the pathology of angina pectoris was properly understood.

Dr. COLBECK considered that "pain in the heart" was the main factor in the symptoms of an anginal attack. He thought that any theory of explanation of the condition must account for the fear of impending death.

Sir JOHN BROADBENT said that there was a great deal still to be learnt about the ætiology and pathology of angina pectoris. He thought that most attacks were due to a spasm of the vessels induced by cold and exertion.

Dr. BEZLY THORNE thought that distension of the heart was the true cause of angina pectoris. He spoke of the presence of tender areas at the apex beat, over the third left costal cartilage, and over the lower part of the sternum. He advocated the use of blisters here in the treatment of the condition.

Dr. EWART considered that the influence of respiration on angina pectoris was not sufficiently taken into account. He thought that it was possible that spasm of the diaphragm might, in certain cases, account for some of the pain present in an anginal attack.

#### GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD NOVEMBER 24TH, 1909.

Dr. MUNRO KERR, President, in the Chair.

PROFESSOR MURDOCH CAMERON and Dr. ROBERT JARDINE showed some interesting cases, and the latter gave a practical

#### DEMONSTRATION OF THE OPERATION FOR CÆSAREAN SECTION.

Professor Cameron was the first member of the profession to perform Cæsarean section in Scotland, and since that time it has become a common operation by the members of the maternity staff, scarcely a week passing without one or two cases.

Dr. Jardine performed the operation with his usual amount of skill, and seems to be as much at home with Cæsarean section as the general practitioner does with an ordinary labour, and on one occasion Dr. Jardine had the experience of performing this operation three times in 24 hours.

The operation seems to the general practitioner a very formidable one, but when he has seen one performed there is no reason why in the wayside hamlet he should not undertake it himself. The most necessitous part of the whole proceedings seems to be in the need of a good assistant, and this the country practitioner generally obtains from his nearest professional brother, or from the district nurse who usually has a maternity training.

#### LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD NOVEMBER 18TH, 1909.

The President, Mr. T. H. BICKERTON, F.R.C.S., in the Chair.

MR. THOMAS GUTHRIE read a note on the removal of a tooth-plate which had remained impacted in the œsophagus for three weeks, by means of Bruning's œsophagoscope. The instrument was demonstrated, and radiographs by Mr. C. Thurstan Holland, showing the tooth-plate in the œsophagus were exhibited.

Dr. W. B. WARRINGTON made some remarks on the results of treatment in some of the grave cases of diabetes mellitus. His statement was illustrated by lantern slides of charts showing various diets and the results of usage.

Dr. F. H. BARENDT showed a child suffering from erythema multiforme.

Dr. NATHAN RAW showed the brain of a child, æt. 12½, who had died from hæmorrhage into the right lateral ventricle.

Dr. BRIGGS read a paper on the

RESTORATION OF THE FEMALE PELVIC FLOOR BY OPERATION OR AN EXTENDED PERINEORRHAPHY. The object of the paper was to urge, on anatomical and clinical evidence, that:—

(a) Reparable damage (mainly obstetrical) to the pelvic floor, calls for a prompt remedy during the parous period of life.

(b) Irreparable atrophy of the pelvic floor is a consequence of the still too frequent postponement of radical operative treatment until the post-parous period of life.

(c) Modern advances in anatomical knowledge and in surgical methods justify an earlier restoration of the pelvic floor.

(d) Loss of tissue by excision of any portion of the vaginal walls is unnecessary and no longer an argument against operation during the parous period of life.

(e) A safe, simple, and effective operation was described.

The paper was discussed, and Dr. Briggs replied.

#### CENTRAL MIDWIVES BOARD.

A PENAL SITTING WAS HELD ON DEC. 1ST AND 2ND.

Dr. CHAMPNEYS in the Chair.

#### PENAL PROCEEDINGS.

THIRTY women were cited to appear before the Board, of whom 11 were struck off the Roll, 5 were censured, and 6 cautioned; 2 were allowed to retire voluntarily, and in the remaining 6 cases sentence was deferred for three months, pending further evidence from the local supervising authorities.

The Hertfordshire County Council, who sent up two cases, sent also their Clerk, Mr. Longmore, with Miss Burnside, Inspector of Midwives, to ask the Board to reconsider their decision of October 7th—viz., "That local supervising authorities be not allowed a hearing in penal proceedings before the Board except by special leave of the Board, which may be given when, in the course of such proceedings, charges are made against an authority or its officers, to which an answer may reasonably be expected." Mr. Longmore pointed out that his Council were anxious to help the Board in the administration of the Act, and they felt that the person making the charge against the midwife in the first place—i.e., the L.S.A. inspector—should be the person to make the charge before the Board; the Council further felt it was but right that the midwives charged before the Board should be given a chance of appearing in person. The Council were therefore ready to pay their expenses, and the expenses of necessary witnesses, in order that the whole thing might be done in as fair a manner as possible. He asked the Board, on behalf of his Council, to give this suggested procedure their careful consideration.

In dealing with one case the CHAIRMAN drew attention to its educational value. The midwife, who had carefully abstained from making any vaginal examinations, had been eight hours at a labour before discovering an abnormal presentation, when she sent for medical help. The doctor found a transverse presentation, the child impacted, and a hand presenting. Dr. Champneys cited this case as a proof that those who advocate external examination *only* are responsible for the lives of a good many infants.

## CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

#### FRANCE.

Paris, Dec. 5th, 1909.

#### IODINE IN SURGERY.

IODINE, as is well known, is a powerful antiseptic, but little toxic, and much cheaper than certain agents in current use, as oxygen water for instance; hence its employment in surgery is gaining rapidly in favour.

Dr. Lance gave recently, in the *Gazette des Hôpitaux*, a few practical indications which merit reproducing.

One of the most active effects of iodine resides in the vapour it gives off at the temperature of the body, as obtained, for example, when iodine cotton wool is applied to the skin. It is in this form that iodine penetrates most easily the tissues. However, its employment under this form is very limited.

The following are some of the principal formulæ used in surgery:—

Iodine, 1 grm.  
Iodide of potassium, 2 grm.  
Water, 300 grm.  
(Lugol-Gram solution.)

Tincture of iodine, 6 grm.  
Water, 1,000 grm.  
(No. 1, strong.)

Tincture of iodine, 3 grm.  
Water, 1,000 grm.  
(No. 2, moderate.)

Tincture of iodine, 1.50 grm.  
Water, 1,000 grm.  
(No. 3, weak.)

For many years the solution of Lugol-Gram was employed for sterilising catgut. Claudius, of Copenhagen, was the promoter of this method; gum catheters and bougies are also left in this solution for five or six hours before using.

To disinfect the hands of the operator, Dannreuther advises plunging the hands for one or two minutes, after a good washing in soap and hot water, in the watery solution No. 2. The hands are but slightly coloured, and if necessary the stain can be easily removed with a weak solution of ammonia.

Painting the skin with tincture of iodine rapidly disinfects, and is of great value in cases of more or less septic wounds or sores of the hands, feet, legs, and scalp of working men. By applying the tincture around the edges, the wound can be sutured with confidence of obtaining reunion by first intention. The same treatment is now generally used for local disinfection of the skin before operating. By previously washing with soap and water, and rubbing with ether to remove the grease, the penetration of the iodine is much facilitated. For Grossich, a simple application without any preliminary, is quite sufficient.

Applications of tincture of iodine for erysipelas are very effective; the same may be said for the treatment of lymphangitis or buboes. In hygroma, synovitis, arthritis, tincture of iodine acts as a revulsive. Better results, however, would be obtained by the solution of Elsberg:—

Iodine, 2 grm.  
Ether, 5 grm.  
Proof spirit, 5 grm.

A number of infections of the skin are treated at present by applications of tincture of iodine. Boils are arrested in their development by a mixture of iodine and acetone:—

Iodine, 4 grm.  
Acetone, 12 grm.

while anthrax is treated successfully with interstitial injections of the tincture of iodine after incision.

As a parasiticide for malignant pustule, actinomycosis, sporotrichosis, etc., a strong solution of iodine,

Iodine, 1 grm.  
Iodide of potassium, 2 grm.  
Water, 100 grm.

acts almost as a specific.

As a caustic, tincture of iodine is commonly employed in injections for hygroma and hydrocele, but Schiassi, of Bologna, injected successfully several times, the above strong solution into the saphena vein for varicose veins.

In gynaecology, tincture of iodine finds many uses. A plug of cotton, steeped in a mixture of glycerine and iodine (1-10; -20-30) is frequently employed in infections of the uterus and the pelvis. For puerperal infection, iodine is freely used, especially in Italy, where the method is known under the name of Mergari.

For the last three years certain surgeons employ iodine exclusively as an antiseptic, in major operations. The hands are rinsed with solution No. 2; the skin over the region is painted with tincture of iodine; iodide catgut is used for ligatures and sutures; a suppurating cavity discovered in the course of the operation is sponged out with No. 2 solution; the line of suture of the peritoneum is painted with No. 1 solution, and that of the skin with tincture of iodine on the third day after the operation, and again when the sutures are being withdrawn. By this means an ideal linear cicatrix is obtained.

#### CANCER OF THE CERVIX.

At the recent Congrès de Chirurgie, M. Jayle communicated a series of 120 cases of cancer of the cervix. He distinguished four degrees or stages in the evolution of the disease. In the first, the cancer is very limited and ablation easy; it is also easy in the second degree, where the cervix is more or less invaded; in the third degree, where the large ligaments begin to be infiltrated, the neoplasm may be removed, yet without injury to the neighbouring organs. In the fourth and last stage an operation is hardly advisable.

The influence of the menopause on cancer of the cervix is certain, but not preponderant. Virginity preserves from the disease, but women who have never been pregnant are as much exposed as the others. Heredity is frequent. Fibroma and cancer have no common causal relation. Women, predisposed by heredity or weakened by general or local maladies are particularly predisposed to cancer of the cervix.

If the *début* is always insidious, the period of latency does not exceed a few months. The warning symptom, in three-fourths of the cases, is hæmorrhage, more or less abundant, appearing between the regular periods or after coitus. In other cases, sanguinolent or yellowish discharge is the symptom that should attract attention.

Patients generally retard coming for examination, either from negligence or that they believe the unusual symptoms due to the approaching menopause, or, again, they are reluctant to undergo examination.

In every case, said M. Jayle, where a woman complains of "losses," pains down the thighs, in the back, the abdomen, stomach, or intestines, an examination should be made.

#### GERMANY.

Berlin, Dec. 5th, 1909.

#### THE SIGNIFICANCE OF THE RED BLOOD CORPUSCLES FOR DISEASES OF URINARY ORGANS, AS WELL AS FOR THE HUMAN BODY GENERALLY

AT the Medizinische Gesellschaft, Hr. Otto Loose spoke on this subject. He said that in his histological studies into recovery from diseases of the urinary organs, he had met with conditions that were not in agreement with our present views in regard to blood cells. In all cases of recovery, on looking into the dark field, nuclei were seen to develop in the blood discs, and these, according to the cause of the different nucleus formations, formed the commencement of a further development of red blood corpuscles. Out of such red blood corpuscles that had become nucleated there then developed multinucleated white blood corpuscles as well as the cells that had been designated as lymphocytes and myelocytes, etc. The further development was dependent on the cause of the disease as the releasing factor, as well as on chemical and physical influences.

Moreover, the speaker had found cells in many other organs and tissues, the development of which out of red blood discs he believed he could prove, and especially the development of spermatozoa and their initial stages could be traced back to them. In a large measure also they participated in the formation of tumours.

He saw in these discoveries the answer to the question as to the mode of action of natural and artificial hyperæmias, and in this way he had found a pathway for the study of the action of medicines on morbid processes. The address was illustrated by a large number of drawings projected on to the screen.

Hr. Skaller followed with a paper on the

ORIGINATION AND TREATMENT OF EXCESSIVE SECRETION OF GASTRIC JUICE IN HEAVY SMOKERS.

He said that the mischief caused by steady smoking might be either direct or indirect. As an illustration he mentioned the eye. Injury to the conjunctiva from tobacco smoke was direct, injuries to the optic nerve were indirect. These followed from the reception of the poisonous constituents of tobacco into the blood current, and were a part of the general intoxication. The most constant functional disturbance was excessive secretion of gastric juice, and his aim had been to prove the connection between the phenomenon and excessive use of tobacco. For this purpose the smoke of a cigar was passed through 20 ccm. of water, and this was injected into a dog. It was shown that the secretory mechanism of the dog was extraordinarily sensitive as regarded the smoke from cigars or cigarettes. This tobacco water caused hypersecretion of gastric juice in the dog, and he claimed that it did so also in the human subject. (If the dog had been habituated to the use of tobacco for a few years, the result might have been different.—CORR.)—The hypersecretion of heavy smokers was not, therefore, of reflex origin, or, at least, reflex only, but a part of a general intoxication. Exemplified on the eye, it was not the direct injury to the conjunctiva, but the indirect injury to the optic nerve. If smokers suffered from gastritis, it was not due to the hypersecretion, but in spite of it. On making inquiry into which of the constituents of tobacco smoke it was that caused the mischief, it was found that there was none when tobacco free from nicotine was used, whilst the injection of nicotine itself set up a train of symptoms nearly identical with those caused by the tobacco smoke water. It was the nicotine constituent, therefore, that did the harm. The other constituents of tobacco smoke—sulphuretted hydrogen, sulphuric acid, carbon monoxide, and pyridin—were irrelevant as regarded the stomach. The contained coal tar oils might set up a pure gastritis, but they were not poisons.

Further inquiry was made as to whether the poison acted on the innervation of nerves or on the parenchyma of the glands. As the effect was not produced in animals that had been atropinised, and as, after injection of Liebig's meat extract, it appeared in spite of atropinisation, he believed that the hypersecretion was due to disturbance of innervation. Considering, also, that the action took in dogs with ("nervelosen") small stomachs, he believed that the ganglia that were seated in the walls of the stomach were the first to be affected by the nicotine irritation.

As regarded treatment, in the worst cases abstinence from smoking was desirable. In milder cases it would be sufficient to abstain one or two days a week, to enable the blood in the circulation and in the liver an opportunity of getting freed from the poison. He pointed out the known harmfulness of cigar stumps, in which there was an accumulation of nicotine, which for this reason it was harmful to keep in the mouth too long or to continue chewing the stump after the cigar had gone out.

So-called "moist" smoking also favoured the entrance of nicotine into the circulation. On the other hand, a cigar after a full meal was all right, as increase of the gastric secretion was then desirable.

Dr. Julius Citron followed with some observations on

TUBERCULIN TREATMENT.

He said that two tuberculins were to be distinguished, the Old Tuberculin and the New (bacillus emulsion). Tuberculins were not toxins, nor endotoxins, but an approach to the aggressins of the tubercle bacillus. He distinguished three reactions, that at the site of the puncture, that at the seat of the disease, and the fever. The curative effect depended partly on the disease reaction. Old tuberculin had the stronger action on the diseased parts, and the speaker recommended the use of it. As the injection set up infiltrations readily, they used a modified preparation at the Charité that was borne almost without any reaction at all. He started with the smallest doses, and gradually went on to larger, but never to large doses. It was best to inject at intervals of five,

six, and more days, as then the formation of protective material was attained. Only high fever was a contra-indication of injection; pulmonary hæmorrhage was not. The early stage of tuberculosis offered the best chance of recovery; pronounced tuberculosis a moderate chance; with cavities the chances were poor. The treatment must be continued as long as there were any symptoms, and the commencement must be made in an institution. There was no biological criterion for the success of tuberculin treatment; we could only fall back on the clinical symptoms.

AUSTRIA.

Vienna, Dec. 5 h, 1909.

EPIDEMIC POLIOMYELITIS.

At the Amts Aerzte Congress, Fürntratt read an exhaustive paper on the infectious nature of poliomyelitis, first described by Prof. O. Medin, of Stockholm, in 1878, and reported to the Berlin Congress in 1890. At this meeting he related 44 cases that had come under his personal notice in the summer of 1878 in the town of Stockholm alone. He affirmed that the onset and course of the disease were variable, but the majority of the symptoms were of a spinal nature, although he was convinced the cerebrum was involved as well as the peripheral nerves. Prior to this description, Jacob von Heine, of Kannstatt had met with a number of cases in 1860, which he defined as a spinal disease in childhood, and the sections obtained at the time clearly proved to be poliomyelitis acuta anterior.

Since then reports of epidemics of the disease have come from the south of France, America, and Norway, but the favourite home of the disease seems to be the Scandinavian "Halbinsel."

In the Swedish epidemic Wickham records 1,000 cases which he traced as having originated from one individual case that led him to the conclusion that the disease was infectious.

In Austria the disease seems to have been first observed in 1898 in an aggravated form and in large numbers, this also pointed to a contagious nature.

Since 1904 Vienna has been visited more or less every summer and autumn by the disease, this gives the appearance of a seasonal incidence, although in Steyr, a small town in Upper Austria, an epidemic occurred in the months of October in 1908 and 1909, where 50 cases occurred, with 12 deaths.

In Styria an outbreak occurred last year, commencing in the month of July, spreading over the whole of the Principality; by the end of October 310 children had been affected, 54 of whom were in the town of Gratz. Closer observation confines the greatest number to August and September, the numbers sinking rapidly in October, and disappearing entirely during the winter months. We must admit that the epidemic in the little town of Steyr was the exception to this rule, as October showed the greatest number.

Since Mekman's time little has been added to the symptomatology of the disease. After an initial prodroma of fever resembling influenza, with general malaise, pain in the limbs, neck, and back; sometimes angina, other times diarrhoea, with intense headache and stiff neck the disease is ushered in when the patient has reached the juvenile age. The pains are so severe in the latter that morphia injections are necessary to give relief. The paralysis that follows is usually confined to the neck and hips, preventing the patient from sitting upright. There are other cases with severe neuritis, facial paralysis, and not infrequently paralysis of the cerebral nerves, which is usually associated with the meningeal form. Another complication accompanying these disturbances is the temporary retention of the urine; also a form of herpes zoster over the paralysed extensor muscles.

The mortality is variable, but the most reliable statistics to hand are those given in the Styrian cases. Of the 310 attacked 39 died, or a percentage of 12.5; six of these deaths occurred under 6 years of age, twenty-two between 6 years and 14 years, and ten over that age. Death usually occurs from the paralysis rapidly invading the respiratory apparatus or centres of respiration. The lecturer had often seen the paralysis

invade the various organs slowly, thus resembling Landry's paralysis. Death is often rapid, occurring on the first or fourth day of the illness. We may correctly term it a child's disease, occurring most frequently between 5 and 15, after which it gradually disappears.

Fürntratt agrees with Wickman in the manner of attack and the infectious nature of the disease. He has seen several sisters attacked, also neighbouring children that had visited others attacked. In one case he saw two children who had lain in a bed from which a poliomyelitic case had been taken, and both were afterwards afflicted with the disease. On the other hand, no case has been met with where the disease has radiated from a centre, nor can it be attributed to school contacts; on the contrary, the disease gradually disappeared in Gratz when the school resumed after the holidays. Another strange coincidence in the Gratz outbreak was that none of the small industrial towns around Gratz had a single case to record. Again, 15 of the cases admitted into hospital were taken from families where no others were affected, although no disinfection or isolation of the other members had been practised. In the largest families never more than two were affected, and these were frequently females. In all these cases no contacts could be clearly established, nor could the origin be satisfactorily traced to a preceding infection; in this we entirely differ from Wickman in the Swedish epidemics. Although we were unable to follow up a chain of contacts, we were persuaded that an appearance of infection did exist, but we must confess these were the exceptions. As a rule, the disease invades a wide area, probably attacking the more susceptible individuals, these may be few in some neighbourhoods and plentiful in others, the infection passing in this way from one person to another. Be this as it may, the infectious virus is still unknown and its transmission a mystery. Until the bacteriologist lifts the veil, poliomyelitis will remain a puzzle, but data such as have been obtained in Styria last year will go far to aid in the solution of this difficult problem.

### FROM OUR SPECIAL CORRESPONDENTS AT HOME.

#### — EDINBURGH.

**CREMATION SOCIETY IN EDINBURGH.**—Dr. Aitchison Robertson addressed a meeting in Edinburgh on December 3rd, in furtherance of the progress of cremation. He advocated cremation from an economic, sentimental, and hygienic point of view, and after pointing to the dangers of an aggregation of bodies in graveyards, dealt with the objection that cremation destroyed evidence of crime, by showing that the method of death certification prior to cremation was so carefully guarded as to render it almost impossible that a crime could pass undetected. The practice of cremation had grown slowly in England, but the numbers of cremations had doubled in the last ten years, and altogether, up to the end of 1908, the number had been 7,264. This fell far short of Germany, where cremation was on the increase, there having been 2,977 cremations in 1907, and 4,050 in 1908. It was stated, also, that the cost of a handsome urn in a permanent niche was very much less than the simplest form of earth burial. On the motion of Dr. Burn Murdoch, supported by Dr. Robertson, Medical Officer of Health for Leith, it was agreed "That an Edinburgh Cremation Society be formed to promote the practice of cremation and burial reform, and that the Committee already appointed take the necessary steps to complete the formation of the Society, and call a meeting at which a constitution will be adopted and office-bearers appointed."

#### GLASGOW.

**DIAGNOSIS OF INFECTIOUS DISEASES.**—Dr. Chalmers, Medical Officer of Health for Glasgow, in his report to the Health Committee of the Corporation, reminded medical men of the difficulty of diagnosing ill-defined cases of typhus fever. Dr. Chalmers referred to the

occurrence of several ill-defined cases of typhus fever, which had occurred in the Garscube Road district of the city. In Bridgeton a similar group of cases had occurred in the interval, and in this district the earlier cases appeared to have been less defined than some of those which had escaped notice in connection with the Garscube Road cases. From notification of one of the present group of cases it was ascertained that certain illnesses of an unknown character were occurring in a friend's house in the same street. On visiting the latter family four persons—the mother and three children—were found to be ill, and it was also ascertained that a married daughter had been removed to the Eastern District Hospital two days before, where she had been admitted as suffering from pneumonia, but the Medical Officer's department found to be under treatment as probably suffering from typhoid fever. All five persons were placed in the Fever Hospital under observation, and the first patient's illness became definitely typhus fever, and the others were obviously of the same character, although less well marked. Another case arose from a visitor to the house of the first patient, who (the visitor) on his (the patient's) admission to hospital was removed to the Reception House for observation. While all of these cases were, in a sense, inter-related, all of them, except the last case, should be regarded as having a common origin, which had not been definitely discovered, although it had to be noted that another member of the family had been admitted to hospital and certified as diphtheritic, but who presented symptoms of an anomalous character, and which were not inconsistent with ill-marked typhus fever. Dr. Chalmers states that the obvious difficulty which exists, even in hospital, in recognising such cases, may serve as an additional reminder to practitioners that typhus fever is present in a considerably modified form both in the Northern and Eastern Districts of the city.

#### DRASTIC ACTION BY THE EASTERN MEDICAL SOCIETY.

—At a meeting of the Society dealing with the recent part time school appointments of the Glasgow School Board, Dr. Millar Semple gave a *résumé* of the situation, including the resolution of the meeting of the general practitioners held in the Faculty Hall, when a motion was passed, with only one dissentient, that the salary offered was inadequate, and that the practitioner should not apply for such posts. In spite of this motion, Dr. Millar Semple stated that certain members of the Eastern Medical Society had applied for and obtained these school appointments, and still held them. These medical practitioners were called upon to offer an explanation as to why they had accepted the posts. After a short discussion, a resolution was moved that those members of the Society who had accepted these appointments should be called upon to send in their resignations to the School Board, or that they should no longer be admitted to the benefits of the Society, and this motion was carried by a majority of over 20. An amendment was proposed that the Society should censure its members who had accepted the appointments, but this was defeated.

#### SUGGESTED AMALGAMATION OF GLASGOW INFIRMARIES.

—At the annual statutory meeting of the Victoria Infirmary on December 2nd, the Chairman threw out the suggestion that some scheme of joint management of the Royal, Western, and Victoria Infirmaries might be practicable. All three institutions rendered the same kind of service, dealt with the same problems, had the same system of management and equipment, and from the standpoint of economy he thought amalgamation would be an improvement. Their incomes were not increasing as he would like, and benefactors were often brought face to face with the invidious duty of allocating their gifts among the three institutions. He suggested that all subscriptions should be pooled, and a general Board appointed with supreme control. The special supervision of each hospital would be delegated to a sub-committee.

**NOTIFICATION OF TUBERCULOSIS IN GLASGOW.**—At a meeting of the Glasgow Town Council, on December 2nd, it was resolved, with only one dissentient, to apply the Infectious Disease (Notification) Act to tuberculosis of the lung for a period of three years. Notification is estimated to cost £1,400 per annum.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### THE GENERAL MEDICAL COUNCIL AND QUACKERY.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—Dr. Latimer in his excellent speech at the St. James's Vestry Hall on November 22nd clearly explained that the General Medical Council possessed no statutory powers enabling it to interfere with unqualified practitioners, or with the purveyors of fraudulent quack medicines and apparatus; but he omitted to mention that the Council was in no way debarred from using its influence in promotion of new legislation to deal with these evils, and that until pressure was brought to bear the Council had consistently ignored the whole question. The Council of the British Medical Association, itself excited to action by the stimulus of its Divisions, addressed the Medical Council; the Medical Council, thus roused, approached the Privy Council, which, in its turn, has set on foot an inquiry through Medical Officers of Health into the extent and effects of unqualified practice. The General Medical Council and the Privy Council both left out the quack medicine traffic, this not having at first been included by the British Medical Association. The Council of the Association is, however, now convinced that any legislation against quackery which did not include the traffic in quack medicines and apparatus, must, as I have always insisted, prove largely futile, since a vast amount of illegal practice is carried on under the cloak of this trade. The questions in the House of Commons by Captain Craig, referred to by Dr. Latimer, which elicited the important statement by the Home Secretary at a Select Committee on quack medicines should be appointed next Session, were prompted neither by the General Medical Council nor the British Medical Association. The episode served to show that the facts need only laying before the Legislature in incontrovertible form to compel attention; it suggested that if the Medical Council, supported as it is by the British Medical Association, would exert itself, it could at least obtain the appointment of a Royal Commission to inquire into the entire question. The evidence for medical law reform is overwhelming, but largely owing to the fact that the majority of newspapers are suborned by quackery, the case can be publicly stated only by means of a Royal Commission. The exposure, as I have so often repeated, would prove beyond doubt that reform would confer upon the public advantages far outweighing professional interests, and that improvement of the status of the legitimate practitioner would be as much to the advantage of the people as to that of the profession. It is within the power of Dr. Latimer to urge these considerations upon the Medical Council, and it is to be hoped he may feel disposed to do so.

I am, Sir, yours truly,

HENRY SEWILL.

The Old Rosery, Redhill, Surrey,  
November 29th, 1909.

### THE JUBILEE OF THE DENTAL CHARTER.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—The Dental Surgeons have shown themselves desirous of commemorating the Jubilee of their Charter, and the Royal College of Surgeons of England, as the first examining body to grant degrees in dental surgery, has endeavoured to show its interest in this branch of the profession, first, by accepting the trust of the Odontological Museum, which is now accommodated in a room adjacent to the Hunterian Collection, and secondly, by entertaining the leading members of the profession at a dinner within the precincts of the College.

I would venture to suggest that this movement might well be directed towards a more permanent memorial of the Jubilee of the Dental Charter by establishing a

"Research Scholarship" and demonstratorship in connection with the Dental Museum.

There are already two small endowed prizes, the Tomes and Cartwright prizes, administered by the College, the one awarded every third, and the other every fifth year; but the dental profession is deserving of something of a much wider scope than these for the stimulation of research, and for the higher teaching of its scientific branches.

My own view favours a far more ambitious scheme than anything in the form of a mere prize, whether awarded after examination or conferred in recognition of original work completed. I would ask for the modest sum of £10,000 to endow a research and teaching demonstratorship in connection with the Dental Museum. In this way not only would a scientific worker be secured, but he would by his demonstrations attract the students from the various dental hospitals to study in the Dental Museum. Such a sum could, I am sure, be easily collected from among the dental surgeons alone; but if they were to impress upon their patients the necessity of endowing dental research, there need be no hesitation in raising the sum I have suggested to £50,000, whereby not only research and teaching demonstratorships might be established, but travelling scholarships might be founded, which would be of great advantage in keeping English dentistry in touch with that of foreign countries.

It is some twenty-five years ago since I first began to advocate the bringing of the dental surgeons back within the pale of the profession, and giving them the same opportunities as ophthalmic, aural and other specialists—one could scarcely have anticipated so encouraging a development as has occurred within so short a period. The dental surgeons have not been slow of late to seize the occasions for better recognition; and by placing the Odontological Society under the ægis of the Royal Society of Medicine, and by handing over their superb museum to the care of the Royal College of Surgeons, they have shown their desire to be associated with the general body of the medical profession.

Now I think the time has come for the further development of the scientific side of the Branch in which direction several members have already gained great eminence.

Should my suggestion find favour with the dental section of our profession, I should be pleased to co-operate with any interested in this project; but it must be distinctly understood that I write quite unofficially, though I have little doubt that the Council of the Royal College of Surgeons would give its consent to the administration of such a research demonstratorship as that proposed if the money were forthcoming for its endowment.

I am, Sir, yours faithfully,

R. CLEMENT LUCAS.

London, W., November 30th, 1909.

### PROFESSOR JONNESCO'S METHOD OF INDUCING SPINAL ANALGESIA.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—Although by this method (addition of strychnine), which has been lately demonstrated in London, the effect of the analgesic drug upon the respiratory and other vital centres may be counteracted (and spinal analgesia thus rendered practicable in regions where it has hitherto been considered impossible), I cannot but think that as regards punctures above the lumbar region there are risks which do not seem to have been very seriously considered. The author of the method indeed has mentioned the possibility of "pricking" the spinal cord, but this he considers to be of no consequence. How can one ensure, however, that something more than a "prick" of the cord or of its vessels, or injection of fluid into its substance, may not be caused by an "untimely movement of the patient," or unsteadiness of the operator, or by some anatomical or pathological peculiarity interfering with the indications that the required depth has been reached? Also, an error in the preparation of the fluid might entail serious

results in high dorsal puncture—far more so than in the lumbar region. Again, it would be of little use for the respiratory centre to remain active if the muscles of respiration become paralysed—and it must be remembered that a “stillness” and laxity of muscles is commonly brought about by spinal injection as well as a loss of sensibility. In fact, this is one of its advantages in such an operation as suprapubic prostatectomy, for which I have several times performed it. The possibility, however, of artificial respiration becoming necessary with a conscious patient is not pleasant to contemplate.

Professor Jonnesco's reference to the advantage of dispensing with the anæsthetist, “a person often inexperienced, and never responsible,” supplies some clue to the greater favour with which spinal and local anæsthesia is regarded on the Continent, as compared with this country. One can hardly imagine a surgeon holding in London or any large city in this kingdom, a position comparable to that of Professor Jonnesco in Bucharest so describing the anæsthetists with whom he is accustomed to work. As I am informed, in most Continental hospitals mechanical and moral restraints need to be employed as adjuncts to imperfect anæsthesia to a much greater extent than would be tolerated either by our own operators or by our own patients.

I am, Sir, yours truly,  
J. D. MORTIMER, M.B., F.R.C.S.,  
Anæsthetist, Royal Waterloo Hospital,  
St. Peter's Hospital, etc.

December 4th, 1909.

#### ANTI-VIVISECTION IN LANCASHIRE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—The enclosed reports from the *Manchester Courier* and the *Liverpool Echo* exemplify the activity of anti-vivisectionist fanaticism in this county. The meeting in this city was, as you will see, presided over by Dr. G. H. Pinder, whilst the principal speaker was that well-known physiologist (!), Dr. Abi Naar Wall. The latter gentleman is too modest to refer to, much less describe, his own research work, which enables him categorically to deny the value of physiological experiment, and positively to denounce the wanton cruelty of those who pursue it. He takes care to keep clear of a charge of libel by speaking of a class, not of individuals, and there is no means of putting an end to these mischievous propaganda. It seems a pity that the Research Defence Society cannot follow these men about with lecturers on the other side. The effect of the teaching is to imbue the simple and ignorant with a distrust of medical science, and to drive them into the hands of the quacks, including the cancer cures, who “eradicate the disease without the aid of the cruel surgeon's knife”—and other such cruel and cynical rascals.

I am, Sir, yours truly,  
A MANCHESTER SUBSCRIBER.  
Manchester, December 3rd, 1909.

#### OBITUARY.

CHARLES ROBERT BELL KEETLEY, F.R.C.S.  
ENG., L.R.C.P.LOND.

WE much regret to report the sudden death of Mr. C. Bell Keetley, the well-known surgeon, on the 4th inst., at the age of 61 years. Mr. Keetley was born at Grimsby, his father being a shipbuilder, and educated at Browne's School, Grimsby, and St. Bartholomew's Hospital. One of his chief achievements as a student was the taking of the gold medal in anatomy of the University of London. His chief appointment was that of surgeon, since the year 1878, to the West London Hospital, and at the time of his death he had for several years held the senior post. He was also a former President of the West London Medico-Chirurgical Society, with which body he was for many years closely connected. A kindly and genial man in private life, he commanded a wide circle of friends and acquaintances. In spite of an unfortunate

defect in hearing, he contrived to enter fully into, and to discharge, all the duties of a busy social and professional life. He was an old friend of, and a frequent contributor to, THE MEDICAL PRESS AND CIRCULAR. His contributions to surgical literature were numerous and valuable. His “Index of Surgery” reached a fourth edition, and one of his most recent articles on “Appendicostomy” attracted an unusual amount of attention.

ROBERT MARCUS GUNN, M.D., M.B.ED.,  
F.R.C.S.ENG.

WE regret to announce the death of Mr. Marcus Gunn, the well-known ophthalmic surgeon. He was educated medically at Edinburgh, London, and Vienna. During a brilliant professional life he filled many parts and gained many honours. He was Senior Surgeon at the Moorfields Hospital, Consulting Surgeon at the National Hospital for Paralysis and Epilepsy, and Surgeon to the Westminster Ophthalmic Hospital. He was late Arris and Gale Lecturer at the Royal College of Surgeons of England; Bowman Lecturer, Ophthalmological Society, 1900; President, Ophthalmological Society; Ophthalmic Surgeon to the Great Northern Central Hospital, and the Hospital for Children, Great Ormond Street. He made many valuable contributions to ophthalmic literature, among those best known may be mentioned the article, “Diseases of the Eye,” in “Treves' System of Surgery,” and “Retina,” in the “Encyclopædia Medica.” He was co-editor of “Gowers' Medical Ophthalmoscopy,” 3rd edition, etc., etc. A man of wide culture and charming personality, his death will be regretted by many friends.

#### REVIEWS OF BOOKS.

##### SEVEREST ANÆMIAS. (a)

IT is in some respects regrettable that Dr. Hunter has chosen to issue his latest work on anæmia in successive volumes. It would, we think, have enabled readers to form a better estimate of his views had he given them to us at once in their entirety. The present volume deals with the evolution of our knowledge of the type of anæmia described by Addison, and commonly known as “pernicious anæmia,” a name which Dr. Hunter discards as having acquired a connotation wider than the original conception of Addison. Dr. Hunter's long and valuable study of the hæmolytic nature of the disease is too well known to require more than mention. The volume before us does not contain so much in the way of original data (for these we are referred to his previous book), as a lengthy argument intended to clear up the confusion which he finds has been introduced into the conception of pernicious anæmia by the hæmatological school of workers. The reasoning is not always easy to follow, nor do the charts intended to help the reader materially simplify matters. As we understand it, the position of matters is somewhat the following:—Dr. Hunter, and with him most English physicians at least, regard the disease described by Addison as a definite entity. The hæmatological school assert that the characteristic feature of an anæmia they identify with this Addison's anæmia is a megaloblastic degeneration of the marrow. Dr. Hunter believes that the central characteristic is hæmolysis due to a specific (drain) infection entering through the lesions of a peculiar glossitis; the marrow chain being secondary. By their criterion, the hæmatologists admit certain anæmias which Dr. Hunter rejects, and *vice versa*. On the other hand, notwithstanding Dr. Hunter's observations, many competent observers have failed to confirm the invariable occurrence of glossitis in cases which they identify with Addison's malady, though some of them are ready to go along with Dr. Hunter so far as the question of hæmolysis is concerned. Presumably, some of these cases fall into Dr. Hunter's group of septic anæmias, which fall to be considered in the forthcoming volume.

(a) “Severest Anæmias.” By William Hunter, M.D., Vol. 1. London: Macmillan and Co., Ltd. 1909.

The argument in the present book is complete in itself, but we doubt whether it is possible to come to any conclusion except a merely dialectical one, until we have Dr. Hunter's views on the other "Severest Anæmias" before us. As matters stand, while Dr. Hunter makes out a strong case for the hæmolytic origin of the disease, he cannot be said absolutely to prove his contention regarding specific glossitis. Apart from this special question, the volume is a valuable contribution to the history of a complicated topic. It proves once and finally that the recognition of "essential anæmia" was due to the clinical acumen of Addison, a fact which has been obscured by our German colleagues' weakness for an uncritical "casuistik," and their comparative ignorance of English medical literature.

#### SIGHT TESTING MADE EASY. (a)

THE author, in this small work of 66 pages, deals with the elementary facts of sight testing. The work is obviously elementary—elementary to the extent of being incomplete—in as much as no details are given of retinoscopy. When the "busy practitioner"—the adjective seems almost an anachronism in these days—believes that he has the time and the inclination to add sight testing to the other demands upon his services—it must surely be worth his while, not only in his own interests but in those of his patients, to learn the subject as it is usually taught. The author divides his chapters into two parts (1) Refraction and ophthalmology; (2) sight testing; and in this small compass provides for the "busy practitioner" a well-written introduction to the various forms of ametropia, and the use of lenses for their correction. As such, and as far as it goes, the book, doubtless, will be found useful by those for whom it has been more especially compiled.

## MEDICAL NEWS IN BRIEF

### A Lady Doctor's Action for Alleged Libel.

THE plaintiff, Dr. Martha Adams, sued the defendants, before Mr. Justice Grantham and a special jury in London, to recover damages for an alleged libel concerning her published in an article in *Vanity Fair*. The writer of the article in question, the Hon. Ernest Pomeroy, was the only defendant now proceeded against, the action having been stayed as regards the others.

The defendant pleaded that the words used were not defamatory, and further said that so far as they consisted of statements of fact they were true, and so far as they consisted of expressions of opinion they were fair comments on a matter of public interest.

Dr. Macdonough, examined by Mr. McCall, said he was the district medical officer for vaccination at Twickenham. He had seen a copy of *Vanity Fair* containing the alleged libel. There was no truth in the suggestion that the plaintiff arranged with him to share his vaccination fees with her. It would be a most improper thing to do.

Cross-examined by Mr. Rawlinson.—Vaccination officers sometimes received 5s. a case for vaccinations. Between 1867 and 1898 vaccination was compulsory. From 1898-1907 exemption might be obtained by going before a magistrate in open Court and stating a conscientious objection. Now such exemption might be secured without appearing in open Court.

#### CASE FOR THE DEFENDANT.

The Hon. Ernest Arthur George Pomeroy, examined by Mr. Bartley, said that for many years he had taken an interest in the question of vaccination and anti-vaccination and had written articles from the latter point of view. He had also assisted persons to get exemption from vaccination when possible. Before he saw the article in the *Morning Leader* he had never heard of the plaintiff. On reading the article he wrote

(a) "Sight Testing made Easy." By W. Wright Hardwicke, M.D. St. And., M.R.C.P. Edin. London: J. and A. Churchill. 1909.

to Mr. Hazard, the father of the child referred to, in order to find out whether the facts had been accurately stated. As a result of his experience it was impossible in many districts to get exemption from vaccination under the Act of 1898. He had no personal feeling against Miss Adams when he wrote the article. He was writing against the general danger of vaccination and the danger of enforcing it compulsorily. He wrote in the interests of the poorer class of people and in those of anti-vaccination. He himself held a strong view that vaccination was dangerous. This was based on the minority report of the Vaccination Commission and other sources.

Mr. McCall.—Do you mean that the doctors believe in vaccination because they want to get fees?—Well, poor fellows, they have got to live.

Re-examined.—In writing the article he had no other motive than discussing a matter of great public interest.

His Lordship summed up the case to the jury, who, after a short deliberation, returned a verdict for the plaintiff with one farthing damages. Judgment was given accordingly.

### Notifying Consumption at Glasgow.

BAILIE J. W. STEWART moved: "That the Corporation, as Local Authority for the City and Royal Burgh of Glasgow under the Infectious Disease (Notification) Act, 1889, Order, in terms of Section 7, Sub-Sections 1 and 2 thereof, that said Act shall, in the district of the said Local Authority, apply to tuberculosis of the lung or tubercular phthisis, and that for a period of three years from the expiration of one week from the date of the advertisement to be made in terms of the said Act (Section 7, Sub-Sections 4 and 5)." The resolution, he said, was simply asking the Corporation to give its formal approval to its former resolution, contained in the Health Committee minutes of 1st September, 1909, and approved by the Corporation, 14th October. The statute required that a certain interval should elapse and that a special meeting should then be held for consideration of the matter. If they approved to-day the next procedure was to transmit the resolution to the Local Government Board.

Bailie Paxton seconded.

Mr. Alexander Kennedy said he wished to move an amendment. It might be that the Council had already committed themselves, but he desired that opportunity of pointing out that this would only be the first step to a more important one. If they took the first step they were bound to carry the matter further, and they should realise what a responsibility they were taking in regard to increased taxation. If they were only going to get the individual labelled, without making any provision for treatment, they were doing a great injustice to the individual. Phthisis was not like the other notifiable diseases. It was not a disease that would last for a week but for the whole life-time of the subject. The only method they had of dealing with it was the open-air treatment, and the Council would be obliged to build sanatoria in order to deal with the sufferers.

The Lord Provost: We are not dealing with that.

Mr. Kennedy: I ask the Council to realise that if you take the first step you are bound to make further provision.

The Lord Provost: No. I cannot allow that to pass.

Mr. Kennedy: I move the previous question.

Mr. Battersby said every point that had been raised by Mr. Kennedy had been before the Health Committee frequently.

Mr. Cohen: What was the cost of this notification?

The Lord Provost: About £1,400.

The resolution was then adopted.

The ordinary meeting was afterwards held.

### University of Liverpool—New Lectureships.

THREE new lectureships were instituted by the Council of the University at their meeting on November 30th, on the recommendation of the Senate and of the Faculty of Medicine:—(1) A lectureship in Orthopædic Surgery, to which Mr. Robert Jones,

Ch.M.Liv., F.R.C.S.Edin., was appointed. (2) A lectureship in Physiology, to which the present Assistant Lecturer and Demonstrator, Dr. H. E. Roaf, was appointed. (3) A lectureship in Pharmacology, to which Owen T. Williams, M.B.London., M.R.C.P., was appointed. The lecturer in Orthopædics will deliver a course of lecture-demonstrations during the summer term, which will be open to graduates and undergraduates alike. The lecturer in Physiology will take special charge of the Chemical Physiology Department. The lecturer in Pharmacology was temporary lecturer in the subject during the last two sessions; he will supervise Pharmacological Research, and will hold a class in Practical Pharmacology, which is in the third year of the curriculum for the degree.

#### Cadbury Brothers v. "The Standard" Newspaper.

THE libel action brought by Messrs. Cadbury, of Bournville, against the proprietors of the *Standard*, was, after a prolonged trial, decided on Monday last in a verdict for the plaintiffs against the newspaper, with the nominal damages of one farthing. Heavy damages were not sought by the plaintiffs, but rather a refutation of the slur on their character implied by an innuendo in the newspaper as to their philanthropic action in endeavouring to stop the importation and ill-treatment of slaves in the production of San Thomé cocoa. The defendants denied that the article published by them was open to the construction put upon it by the plaintiffs, and the verdict went to show that the plaintiffs were justified in their action, and that their reputation was too high to necessitate damages. We congratulate Messrs. Cadbury on the result.

#### Provident Surgical Appliance Society.

THE Thirty-sixth Anniversary Festival Dinner of this useful institution was held at the Prince's Restaurant, on Thursday evening last. The chair was taken by Mr. Sheriff Ralph Slazenger. After the usual loyal toasts, the Chairman proposed the toast of "The Society," whose help literally enables the lame to walk, the deaf to hear, and the blind to see. The toast of "The Corporation of the City of London" was proposed by Mr. E. White, J.P., Vice-Chairman of the L.C.C., and responded to in a humorous speech by Mr. George J. Pack.

A sum of £785 was collected and promised in the room. At the same time, however, the Chairman deprecated the idea that all present should think themselves called upon to subscribe at that moment, but he rather advocated the view that the annual dinner was to further and increase interest in the Society, and for this object a subscription booklet was distributed amongst the company present. The Society is for the help of those who try to help themselves, and is not a pauperising institution.

#### London Hospital.

EXTENSIVE alterations have to be continually made at the London Hospital, as at the other large hospitals, to bring the institution into line with modern requirements. The London Hospital, one of the finest in the world, shows that something like £500,000 has had to be spent by the hospital authorities in this way during the past ten years or so. This, in addition to the very heavy annual expenditure of the hospital, has thrown an extremely heavy strain on its resources.

#### Hospital Sunday Fund.

THE report for the current year adopted at a meeting of the Council of the Metropolitan Hospital Sunday Fund shows the confidence which the public have placed in it for so many years. The collections for 1909 have not been quite so large as last year, but the difference is to be accounted for by the falling off in three or four large offertories only, the total amount collected during the year being £72,650. The fund is well supported by the clergy of all denominations, who this year have been collecting nearly £40,000 for it.

#### Royal Institution.

THE eighty-fourth Christmas Course of Juvenile Lectures, founded at the Royal Institution in 1826 by

Michael Faraday, will be delivered this year by Mr. William Duddell, F.R.S., his subject being "Modern Electricity." The course, which will be experimentally illustrated, commences on Tuesday, December 28th, at 3 o'clock, and will be continued on December 30th, 1909, and January 1st, 4th, 6th, and 8th, 1910.

#### Hospital Saturday Fund.

THE income of the Hospital Saturday Fund for this year amounts to £19,734. This shows an increase of £50 on the amount collected in the corresponding period of last year, notwithstanding the fact that the accounts for 1908 had to be kept open a week later than usual. The accounts for 1909 will be closed on January 10th, 1910, and honorary collectors are requested to send in all moneys collected this year not later than that date.

#### Mind Cures.

A REPORT published in Washington estimates that there are 17,600,000 persons in the United States who, instead of calling in a physician when they are sick, resort to some one of the many forms of drugless healing. Of these systems at least two-thirds are "mind cures." Ten years from now, judging from the rate of increase during the last ten years, says the report, there will be 55,000,000 persons relying on non-medical methods.

#### Professor Politzer Jubilee.

PROFESSOR ADAM POLITZER, of Vienna, will tomorrow celebrate the fiftieth anniversary of his graduation as a doctor of medicine, and the occasion will be made an opportunity for according him special honour. At a festival which has been arranged by the leading Austrian otological societies numerous presentations will be made, among them one from the University of Vienna.

#### Middlesex Hospital.

IN spite of great care in regulating the expenses of the institution, the authorities of the Middlesex Hospital have been compelled to spend £12,500 more than their income during the past year, having had to negotiate a loan with their bankers to meet current expenditure; the total deficit at this hospital is therefore now about £20,000.

#### L.C.C. and Slaughter-houses.

THE London County Council, finding that it had no statutory powers, and having regard to the special circumstances of London and to the numerous interests concerned, has resolved to ask the Local Government Board to appoint a departmental committee to inquire into the questions of the establishment of public slaughter-houses in London and of food inspection generally.

#### Trinity College, Dublin.

THE following candidates passed the Final Medical Examination, Part II., Michaelmas Term, 1909:—

Midwifery.—John H. Woodroffe, Ernest W. G. Young, passed on high marks; John G. Dods, Roclaf A. Albertyn, William R. Watson, Perceval G. Leeman, Euphan M. Maxwell, Francis J. A. Keane, Charles Pentland, Reginald T. Vaughan, John B. Burgess, Victor W. T. McGusty, Richard P. Pollard, James H. Crane.

THE assistant-doctors of the Vienna hospitals have passed resolutions which will lead to a strike unless their claims are acceded to. The Municipal Council has refused to consider their claims, and the doctors have decided to give a month's notice as from December 1st.

These medical men demand the regulation of their position with reference to the directors of the hospitals, the full physicians and surgeons, and the *personnel* of the hospitals, also with regard to accident insurance, liability to the State in cases of complaint on account of professional mistakes, leave of absence, and the raising of their salaries from 133 to 200 kronen per month.

## NOTICES TO CORRESPONDENTS, &c.

**✉** CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, 25; Half Page, 23 10s.; Quarter Page, 21 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at 23 10s.; 26 at 23 5s.; 53 insertions at 23, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 6s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

THE EVOLUTION OF SURGERY.—Pasteur's basic discoveries were practically applied first by Lister, who thus started the evolution of latter-day surgery. Ferrier, and other physiologists, experimenting on the brains of monkeys antiseptically, demonstrated fortuitously the practicability of human brain surgery, which is now universally practised.

W. R. MILLER (Liverpool). You may take it as a rule without exception, that anyone advertising himself as a "Dr." or as "Professor" to cure all ailments is a quack. The Oxford Street "Dr." about whose *bona fides* you inquire, is one of the worst type, and you may congratulate yourself on not falling into his clutches, before asking an opinion. We do not give advice by post, but your complaint is one of quite a common occurrence which can readily be remedied by any general practitioner in your locality.

### THE OATHS BILL OF 1900.

THE new Oaths Bill having received Royal Assent last week, it will henceforth be unnecessary to go through the unpleasant and insanitary duty of kissing the begrimed cover of Holy Writ. For years past we, in these columns, and the medical profession in general, have protested against its observance. It affords us great pleasure, therefore, to announce that the Scottish form of taking the oath, with uplifted hand, will be administered as a matter of course.

ONE INTERESTED.—Reliable statistics on the populations of the countries referred to are not to be obtained. The following, however, may be taken as approximately correct:—The United Kingdom, 45,000,000; Japan, 50,000,000; Germany, 65,000,000; the United States of America, 90,000,000. Japan is increasing more rapidly in proportion than the others, Germany being next.

ERRATUM.—In our "Laboratory Notes" last week we referred to the new combination of iodide of potassium with levurine extractive (Coulurioux of Paris) as "iodase"; it should read "iodurase."

## Meetings of the Societies, Lectures, &c.

### WEDNESDAY, DECEMBER 8TH.

ROYAL SOCIETY OF MEDICINE (BALNEOLOGICAL AND CLIMATOLOGICAL SECTION) (20 Hanover Square, W.).—5.30 p.m.: Papers: Dr. Clippington: The Chiltern Hills; Dr. Mahomed: Atmospheric Electricity.

HUNTERIAN SOCIETY London Institution, Finsbury Circus, E.C.).—8.30 p.m.: Mr. E. H. Fenwick: Surgical Aspects of Kidney Disease.

### THURSDAY, DECEMBER 9TH.

ROYAL SOCIETY OF MEDICINE (NEUROLOGICAL SECTION) (20, Hanover Square, W.).—4.30 p.m.: Clinical Meeting. Cases will be shown by Dr. James Taylor and Dr. Wilfred Harris.

ROYAL SOCIETY OF MEDICINE (OBSTETRICAL AND GYNECOLOGICAL SECTION) (20 Hanover Square, W.).—7.45 p.m.: Exhibition of specimens. Short communications by Dr. Philip D. Turner and Dr. A. H. Lewers.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8 p.m.: Card Specimens by Mr. S. Stephenson, Mr. N. B. Harman, and others. Declaration of the Poll of the Society re Amalgamation. 8.30 p.m.: Mr. R. W. Doyne: (1) Description of a Form of Conjunctivitis; (2) A Note on Family Choroiditis (with patient); (3) A Note on Myopic Degeneration of the Lens (with patient); (4) Note on a Form of Iritis. Mr. M. S. Mayou: Congenital Sarcoma of the Orbit. Mr. A. P. L. Wells and Mr. M. S. Mayou: A Round-celled Sarcoma of the Lacrymal Gland.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m.: Dr. W. H. Dolamore: Pyorrhea Alveolaris. Dr. A. Fleming: The Specific Treatment by Inoculation of Infective Conditions of the Mouth.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—5.15 p.m.: Prof. W. Thorburn (Manchester): "Some Points in the Surgery of the Biliary Passages."

HOSPITAL FOR SICK CHILDREN (UNIVERSITY OF LONDON) (Great Ormond Street).—4 p.m.: Lecture (Surgical): Mr. Laue: Some Abdominal Conditions.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.O.).—6 p.m.: Chesterfield Lecture: Fungous Diseases of the Skin—(1) *Tinea Circinata*; (2) *Tinea Imbricata*; (3) *Tinea Versicolor*; (4) *Erythrasma*; (5) *Actinomycosis*; (6) *Madura Foot*.

### FRIDAY, DECEMBER 10TH.

ROYAL SOCIETY OF MEDICINE (CLINICAL SECTION) (20 Hanover Square, W.).—8.30 p.m.: Cases by Mr. H. J. Paterson, Mr. J. B. Lunn, Dr. Milne, Dr. McMullen, Dr. Herringham, Mr. A. Carless, Mr. W. G. Spencer, Mr. J. D. Malcolm, and Dr. Poynton.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Mr. F. R. Cross: The Brain Structures concerned in Vision and the Visual Field. (Bradshaw Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—5.15 p.m.: Dr. R. F. Bashford: "Some Results of the Comparative Biological and Experimental Study of Cancer."

### MONDAY, DECEMBER 13TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—5.15 p.m.: Dr. Fitzgerald Powell: "Some Diseases of the Larynx, with special reference to Hoarseness and Loss of Voice."

### TUESDAY, DECEMBER 14TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—5.15 p.m.: Dr. Percy Kidd: "Some Points in the Clinical History of Pneumonia."

## Appointments.

BOOTH, N., M.B., Ch.B.Vict., Senior House Surgeon to the Manchester Royal Infirmary.

FRASER, MARK S., M.B., Ch.B., D.P.H., F.R.C.S. Edin., House Surgeon at the Paddington Green Children's Hospital.

McMUTRIE, A. C. B., M.B., Ch.B., D.P.H., F.R.C.S. Edin., House Physician at the Paddington Green Children's Hospital.

NICHOLLS, G. E. E., M.B., Ch.B.Vict., House Physician at the Manchester Royal Infirmary.

PLATT, H., M.B., Ch.B.Vict., Junior House Surgeon at the Manchester Royal Infirmary.

SMALLEY, A. A., M.B., Ch.B.Vict., House Physician at the Manchester Royal Infirmary.

TATTERSALL, N., M.B., Ch.B.Vict., House Physician at the Manchester Royal Infirmary.

## Vacancies.

City of Leeds Infectious Diseases Hospitals and Sanatorium.—Resident Medical Officer. Salary £120 per annum, with board, lodging, and washing. Applications, to the Medical Superintendent, City Hospitals, Searcroft, Leeds.

County Council of Lanark.—Assistant Medical Officer of Health. Salary £170 per annum, with travelling expenses. Applications to the County Clerk, County Offices, Hamilton.

Kent County Asylum, Chatham.—Third Assistant Medical Officer. Salary £145 per annum, with board, quarters, attendance, and washing. Applications to Medical Superintendent, Chatham, near Canterbury.

Lancashire County Asylum, Winwick, Warrington.—Assistant Medical Officer. Salary £150 per annum, together with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent.

Lister Institute of Preventive Medicine.—Biochemical Department.—Senior Assistant. Salary £350 per annum. Applications to the Secretary, Lister Institute, Chelsea Gardens, London, S.W.

Enfield and Edmonton Joint Hospital Board.—Resident Assistant Medical Officer. Salary £150 per annum, with rooms, rations, and washing. Applications to T. W. Scott, Clerk to the Board, Public Office, Enfield, Middlesex.

Southampton Free Eye Hospital.—House Surgeon. Salary £100 a year, with board and residence. Applications to Major R. W. Heathcote, Secretary.

West Herts Hospital, Hemel Hempstead, Herts.—House Surgeon. Salary £100 per annum, with rooms, board, and washing. Applications to Robt. L. Butterfield, Asst. Secretary at the Hospital.

## Births.

FERGUSON.—On Dec. 5th, at the Hydropathic Establishment, Great Malvern, the wife of Dr. J. Newbery Ferguson, of a son (John Douglas).

## Marriages.

WILSON-BERRY.—On Dec. 4th, at St. Paul's, Barrow-in-Furness, Lorton Alexander Wilson, M.R.C.S., L.R.C.P., eldest son of John Forsythe Wilson, M.D., to Kathleen, eldest daughter of the Rev. W. Berry, M.A., Vicar of St. Paul's, Barrow-in-Furness.

WILSON-WARREN-VERNON.—On Dec. 3rd, in the Cathedral, Bombay, Captain Frederic Ernest Wilson, Indian Medical Service, son of Major Wilson, late Scots Greys, to May, only daughter of Hon. William and Mrs. Warren-Vernon, of London.

## Deaths.

KEETLEY.—On Dec. 4th, suddenly, at Brighton, Charles Robert Bell Keetley, F.R.C.S., Senior Surgeon to the West London Hospital, of 56 Grosvenor Street, London, W., aged 61.

## NOTES AND COMMENTS.

### The Patience of Science.

OF all the qualities that go to make up the man of science that of inexhaustible patience is one of the most essential. The life work of a Newton, or a Darwin, or a Lister, or, indeed, of all great men of science, has been built upon a foundation of patient observation. Nowadays the road is somewhat smoother, for the principles of many branches of scientific work are better known, and in many cases research is endowed and there are the contingent advantages afforded by collective investigation. Nowhere has the need of the patient spirit been more brilliantly demonstrated than in the rapidly extending conquest of medicine over infective tropical diseases. The great problem now is, how to eradicate sleeping sickness from Uganda, and it is a great pleasure to record a fresh advance in the attack. One great gap in our knowledge was the failure to discover the pupæ of the tsetse fly which spreads the malady. Early in the present month, however, a number of the pupæ were received at the London Zoological Gardens. The natives failed to find the pupæ, although stimulated by an offer of one rupee a piece for them. It was left for Dr. A. G. Bagshawe to run them to earth in a banana plantation near the shore of Albert Edward, where the larvæ had been deposited, for this particular insect is viviparous. This discovery led to various other investigations of the usual patient thoroughness, as the result of which we may hope that the preventive control of sleeping sickness has been brought well into sight.

### Further Plans.

UNFORTUNATELY for the interests of preventive medicine the banana forms the chief food of the natives in that part of the world, so that to destroy the banana plantations that abound near the lake was out of the question. Professor F. A. Minchin, of the Lister Institute of Preventive Medicine, made the happy suggestion that if fowls were introduced they would probably scratch up and devour the pupæ from the banana rootlets. Then it was found by Dr. Bagshawe that the effective range of the flies from the shore of the lake was not more than a mile. This fact he established by amputating one of the six legs of a number of tsetse flies and releasing the flies which were caught again and identified at various distances from the water's edge. The next step was to remove the huts of the natives beyond this mile zone into a fly-free area. The whole story suggests a kind of scientific chess in which the parasite of sleeping sickness is one of the players. Although now and then the time of waiting between the moves may be tedious, there can be no doubt, judging from previous experiences, which

side will be able to cry "checkmate" at the finish. What would the early fathers of medicine have exclaimed at the spectacle of our best scientific medical men packed off to Central Africa to study the habits of a venomous little fly?

### Evolution at Battersea.

THE Brown Dog statue at Battersea erected to the memory of a certain brown dog and of 232 other dogs "done to death" by vivisection in University College Hospital, a year or so ago became famous, not to say notorious. Now it appears to be evolving into a veritable White Elephant, at any rate, the thing has cost recently some hundreds of pounds in order to keep police on guard near the statue lest perchance some one might damage or deface either the dog itself or the inscription which tells the norrabul tale of woe. At the next meeting of the Battersea Borough Council it will be proposed that efforts should be made to give back this creature to the donors, as its cost for men and watchboxes on the one hand and the obstruction caused to the pathway where it is on the other, are matters that were not in the contemplation of the parties when they accepted the statue. The fact of the matter seems to be that Battersea is beginning to see the affair of the little brown dog in its true perspective. To pay £700 for the protection of a sentimental monument that gives gross offence to many sensible persons is to court the ridicule of the neighbouring parishes less open to the presence of ill-balanced anti-vivisectionists. There never can be enduring peace while so offensive an inscription is flaunted in a public place.

### Vivisection: A New Name Wanted.

THE popular meaning which has unfortunately grown around the word "vivisection" is to be deplored from many points of view. Its original sense in reference to experiment on living animals has become altogether swallowed up by the secondary conception of cruelty attached to it by the apostles of anti-vivisection. Its acquired sense no longer expresses with anything like accuracy (if it ever did) the facts of the case inasmuch as cruelty, that is to say, the causing of unnecessary pain, is avoided by anæsthesia, local and general. Where an anæsthetic is not used the vast majority of operations consist of inoculations involving the mere prick of a pin. The word "vivisection" therefore no longer expresses the meaning that scientific men desire to convey, and any philologist will be doing a service to medical science should he suggest a crisp and adequate new term. It might for example, be replaced by some compound signifying section when anæsthetised or asleep say "somno-

section" or "hypnotomy" or any word of sufficient accuracy and euphony. To our mind the whole vast series of inoculation punctures should be separated from cutting experiments and included under the heading of "vaccination."

#### A Knotty Problem.

THE disquieting fact of the steady decline of the national birth-rate is variously interpreted by different observers, but the problem is one of serious import to all thinking men. The statesman and the statistician may well stand aghast at the future prospect of a vast empire whose dwindling population will find it hard to maintain a foremost place among the powers of the world. On the other hand, the stern moralist reckons little of principalities and powers, attaches supreme importance to the decadence of a race that presumes to limit the number of its offspring. Yet when all is said and done the bare fact remains that the decreasing birth-rate prevails amongst the well-to-do, the thoughtful, the provident, and the more intellectual classes of society, while the high birth-rate is maintained amongst the thoughtless, the reckless, the improvident, and the poorer classes. The indictment against limitation, therefore, is levelled at that portion of the community which represents the brighter and better side of humanity. It is not easy to fathom this point. Perhaps the decrease is symptomatic of the unequal distribution of wealth and the greater demands upon the individual who attempts "to live up to his position." In that case the State endowment of parentage may before long be adopted by our progressive legislators. The thin end of the wedge has been already inserted in the income-tax relief in respect of children proposed in the Budget recently rejected by the Lords.

#### The Daily News Declines.

THE fact is, of course, notorious that one of the chief bulwarks of quacks and of quackery lies in the active and passive help afforded by the lay newspaper press. That attitude is explained readily enough by the enormous sums of money spent in advertisement by irregular practitioners and the vendors of secret medicines and cures. To some extent a few of the leading British newspapers have been induced to fly their colours by the British Medical Association, which has been refused advertisement of its reprint "Secret Remedies" by the *Daily Express*, *Daily Chronicle*, *Star*, *Graphic*, and *News of the World*. The latest additions are bracketed as the *Daily News* and the *Christian Herald*. It is humiliating to think that journals which profess a high standard of ethical morality should refuse to give publicity to a book published in the best interests of the health of the community. The *Daily News* is so sensitively careful of its readers' moral welfare that it will not even publish the betting news. We venture to say that infinitely less harm is done to the public by horse racing than by pitiless frauds that are daily and hourly inflicted upon our fellow citizens of all ages, sorts and conditions by the sordid lies and chicanery of quacks and of secret medicine vendors. We doubt if Mr. Cadbury, who we understand is the proprietor of the *Daily News*, has read the book to which his journal denies publicity, and if he realises in what way the money paid for secret remedies advertisement is obtained? As to the religious journals there could be no fiercer satire upon the difference 'twixt precept and practice than that of the exploitation of a religious publication by a cynical quack.

## LEADING ARTICLES.

### MOTOR CAR TRAFFIC IN TOWNS.

WITH the traffic of public roads, by the nature of the case, must always be associated a margin of accidents to life and limb. Unexpected conditions may suddenly supervene on the part of drivers, of pedestrians, or of the physical environment. Under certain circumstances, such as fog, a slippery roadway, and the momentary negligence or carelessness of persons concerned it would be impossible to avert an occasional disaster. But there are many accidents of an avoidable nature, and these it is the duty of the authorities, both local and central, to endeavour to their utmost power to prevent by wise regulations. The problem of the traffic of a great city is complicated at any time, but of late years it has been rendered much more so by the introduction of the disturbing element of motor traffic into the streets. Not only has the pedestrian to acquire the knowledge of the relations of a new and often noiseless vehicle to his own movements, but he is confused by the varying speeds of horse vehicles, and by the swiftness with which motor carriages dash round corners and convert an apparently safe open roadway into a sudden valley of death. The mortality from this cause has reached a pitch that urgently demands attention both from the London County Council and from the Legislature. The matter has been temperately but firmly dealt with by our contemporary, *The Lancet*, in an editorial of December 11th. The suggestion is therein made that if a census were taken of the accident cases now being treated in the London hospitals it would present some suggestive figures. If this were done for a year it seems probable that such a startling mass of evidence would be forthcoming that the authorities would be compelled forthwith to take some sturdy action. There is already in existence a Highways Protection League, formed of citizens anxious to preserve the safety of the public on the highways. Of the various points that have engaged their attention the two important factors of noiselessness and speed must have been amongst the foremost. Most observant persons—and who is not observant of motors?—must have noted the tendency of motor drivers to assume that there is no need to give any warning in streets or squares that are comparatively free of pedestrians, or in such places when nearly deserted at night. That is precisely the time when the hapless pedestrian is lulled for a moment into a fatal sense of security, and when the motor driver seizes the opportunity of making the most of the apparently free road before him. This dangerous set of circumstances would be more or less minimised by the action of an automatic continuous warning, which need not be of an excessively high or loud pitch, by the automatic record of actual speed at the time of an accident (for which a special meter is we believe obtainable), and by the reduction of speed limit to ten miles an hour. These demands can hardly be called unreasonable when on the other hand the safety of the life and limb of the citizen is at stake. As regards the warning by bell or other contrivance there should be some fixed rule as to its use at street turnings and other defined

places, as well as during the exigences of ordinary street traffic. Moreover, it is plainly useless to sound a warning when the motor is within a few feet of the pedestrian, a practice that is not uncommon with drivers, who afterwards in court assert with truth that the warning had been given, but who neglect to add the material qualification that it was given at such time as to be useless. As to the automatic record of speed ascertainable at any particular moment it may be claimed generally that without something of the kind it will never be possible to establish real control over motor vehicles. It often happens that the only witness as to speed is the driver, who is not likely to advance an estimate unfavourable to himself. As to other evidence there are few persons competent to form a correct conclusion as to speed, quite apart from the mere glimpse that is usually afforded during the sudden spectacle of a street accident. But the fundamental fact remains that motor drivers at a high speed are more likely to cause accidents than those at low speed. That ground, at any rate, seems to be unassailable. Were the same maximum rate of speed imposed upon all motor vehicles as that enforced in the royal parks there can be little doubt that the safety of the citizens of all our great centres of population would be greatly increased. Why should any reasonable person want to travel through the streets at a speed greater than ten miles an hour, especially if he knows that to exceed that speed is to endanger the safety of his fellow creatures? The attention of the London County Council is hereby drawn to the foregoing consideration, in the hope that they will once again address themselves earnestly to the diminution of a danger that, day by day, figures more and more urgently upon the town dweller.

#### THE TOWN PLANNING ACT.

THE Town Planning Bill, after many ups and downs, has come into being as an Act in the last few days of the session. It registers several important changes in the law. The Act, as already noted in these columns, protects the county Medical Officer of Health, as he cannot now be dismissed without the consent of the Local Government Board. It also requires every County Council to have a Medical Officer of Health, who must devote his whole time to his duties and must be supplied with all reasonable information by the medical officers of health of the several districts in the county, while in his turn the county medical officer will report to the Local Government Board. Further, each county council must appoint a public health and housing committee, and to this statutory committee all the council's business in respect of public health and housing is to be referred; any local authority, if called upon, must report to the Local Government Board as to the sanitary condition of their area showing any particulars which may be required. The maxim "every man's house is his castle" is wisely, if unpleasantly invaded, by enlarging the power of entry by authorised persons in order to ascertain the condition of the premises. The liability of the landlord for the fitness of the house he lets for human habitation has been increased, where before

he was only liable if the rent was £20 or less in London and so on, he is now liable for houses at a rent not exceeding in London £40; in a borough or urban district of 50,000 or upwards, £26; and elsewhere £16. This liability extends in virtue of Section 15 throughout the tenancy. Another important provision is that closing and demolition orders need no longer go to a court of summary jurisdiction, the local authority makes the order and the appeal is to the Local Government Board. Back-to-back houses and cellar dwellings are prohibited in future. The ultimate possibility of merging district authorities into the county council is to be discerned in the provision for new houses; if a rural district council refuses to provide necessary accommodation for the working classes of their district the Local Government Board after inquiry can order the district council to do the necessary work, or impose it with consent on the county council. Complaint on the above score can be made by four inhabitant householders, and facilities for carrying out the improvements have been made by making land acquirable by the procedure of the Small Holdings Acts, and extending the period money may be lent from 50 to 80 years. Moreover money left by philanthropic persons for housing purposes will in future be under the eye of the Local Government Board, which can cause the Attorney-General to intervene to facilitate legal action. A cottage, as now defined by this Act, can have a garden of an acre in extent. The provisions relating to town planning are an entirely new feature in this country. Hitherto, a new centre of population like the constitution itself has grown and not been made, now the Local Government Board can authorise local authorities to prepare town planning schemes in connection with land likely to be used for building purposes and so avoid hazardous building, while securing on the other hand sanitary conditions, amenity and convenience. In such planning some may get compensation for depreciation of property, others may have to pay should the land be increased in value.

---

#### CURRENT TOPICS.

---

##### Hop-pickers Typhoid.

THE occurrence of an epidemic of enteric fever at Dudley points the moral as regards the absolute necessity of a rigid system of sanitation in counties as well as in towns. In order to approach a reasonable security against infection the preventive machinery must be comprehensive, co-operative and universal. It avails little to protect a populous city by pure water supply, good drains, and an efficient health administration, if it be liable at any moment to have scarlet and typhoid fever imported by milk from slothful rural farms. At other times the infection having been brought through human agencies, such as small-pox by tramps or, as in the case of Dudley, enteric fever by hop-pickers who have been infected by the impure water of some country stream. The Medical Officer of Health of the last-mentioned town, Dr. Wilkinson, has reported eighteen cases of typhoid within the past five weeks. The whole of the cases occurred in the

Netherton ward, with the single exception of a patient from another part of the town, for whose infection no cause could be traced. Not a single case occurred otherwise in any person who had not been to the hop fields. A number of people had been attacked in the sanitary areas which adjoin Dudley, a fact that emphasises the likelihood of the origin of the whole visitation being due to the agency of water. Both diphtheria and enteric fever have been previously introduced into Dudley by hop-pickers, so that the Local Government Board have every ground for insisting on the future sanitary supervision of the hop farms.

#### The Medical Curriculum.

IN whatever form it appears, a debate on medical education occurs in practically every session of the General Medical Council. A distinction often overlooked in discussions on the subject was pointed out by Sir Clifford Allbutt in the recent session, between the standard which may be properly maintained by a qualifying corporation and the minimum standard which the General Medical Council is bound to set up. In too much of the criticism one hears the Council is blamed for not setting a higher standard than at present. Our own opinion is that the course is already over-loaded, and not with the most important subjects. There is difficulty in making provision for instruction so necessary as that in the art of anæsthetics, while students waste months in learning a useless botany, and a still more useless *materia medica*. It is, as Sir Clifford Allbutt remarked, a grave statement to make that a man cannot be adequately educated in five years. Yet how many men at present conclude their medical course within five years of their starting their preliminary work? The decision come to by the Council that at least two years—twenty-four months—must be left for the final subjects, while excellent in itself, may not improbably have the effect of adding several months to the medical course.

#### The Political Crisis.

It is fortunate for the medical journalist that he stands in a position of complete detachment from party politics, that his duty is to regard the struggles of opposing schools and the strife of faction from the scientific and philosophical point of view. The medical man, however, ought not to shirk the duties of citizenship. He is bound to form an opinion and cast his vote at local and imperial elections; but no one is so able as he to recognise "how small, of all that human hearts endure, that part which laws or kings can cause or cure!" No one is so well able as the medical man to perceive at the present juncture that it matters not so much which party gains the victory, that nearly everything depends upon the use they make of it, and upon the help they may receive from the bulk of citizens in promoting necessary reforms and in administering new laws. All parties are agreed that the social problem, the problem of raising our people to a higher plane of civilisation, dominates everything. It is for this, mainly, that money is wanted. If sanitary laws, sanitary institutions and administration could be brought up to the level of science, a great many of the most glaring social sores would at once be

mitigated, and would soon be cured. Sanitation, in the broadest sense of the word, and education, in the widest and deepest sense of the word, are two of the chief remedies for existing evils. It is, however, a question whether legislation, however wisely constructed, will prove of much avail unless the spirit of the people from above downwards can be roused, and the feeling of patriotism be made to influence all classes. New social laws throw upon local governing bodies more and more work and responsibility, and unless these bodies are manned by independent and capable citizens, inefficiency, if not jobbery and corruption, will mar their labours. It is impossible effectually to legislate in advance of public opinion; the history of local government throughout the country disclosed in these columns from week to week exemplifies and illustrates this fundamental fact, and demonstrates its vital importance.

#### Oysters.

IN view of the latest report from Dr. Collingridge with regard to the traffic in contaminated oysters at Billingsgate Market, the only safe course for medical practitioners at present seems to be to forbid the use when uncooked of this excellent article of food to their patients, until such time as an undubitable guarantee of purity is forthcoming. Oysters form a most admirable item in many schemes of invalid dietary, but when even a remote risk of typhoid fever is involved their use cannot, of course, be entertained. Within the last week or two Dr. Collingridge has informed the City Corporation that a case of illness attributed to oysters was reported on November 12th at Paddington. The oysters had been bought in Billingsgate Market under the name of "Brightlingsea Ports," and were said to be of French origin and to have been relaid at Brightlingsea for more than a year. A sample of oysters from the same source was obtained from Billingsgate and submitted to Dr. Klein, who certified that they were polluted. A case of typhoid fever attributed to oysters was reported from Eastbourne. The patient, had eaten many oysters. These had been supplied by two firms in Billingsgate Market, one being the same as in the Paddington case. These oysters had been sold as "certified oysters from Dutch grounds," which "from analysis are shown to be perfectly pure." In each instance the facts were communicated to the Fishmongers' Company, who are inquiring into them. The action of the Fishmongers Company is so far satisfactory, but until the result of their inquiry is published, and some assurance that polluted oysters do not find their way to retailers through other sources than Billingsgate, the profession and the public will do well to act strictly upon the advice offered at the opening of this paragraph.

#### A Dublin Physician of the Eighteenth Century.

THE by-ways of medical history present much matter of interest—both personal and scientific—to those who wander through them, and we are glad to note that the number of explorers gradually increases. Among the most distinguished Dublin physicians of the eighteenth century—though hardly remembered now-a-days—was Edward Barry,

whose career Dr. Kirkpatrick recalls in the current number of *The Dublin Journal of Medical Science*. A native of Cork, and a graduate of Trinity College, where he probably studied anatomy under Bryan Robinson, Barry, became at the age of twenty, a pupil of the great Boerhaave, at Leyden. He practised in Cork for some twenty years, in Dublin for twenty more, and in London for some eight or nine, spending a few years in retirement ultimately at Bath. In Dublin he occupied a high position in the profession, being Regius Professor of Physic in the University, Physician-General to the Forces in Ireland, and three times President of the College of Physicians. He had a professional residence in College Green, but built for himself a beautiful house in the suburbs, now, curiously enough occupied again by a very distinguished physician. Barry, a singularly handsome man, polished and a shrewd man of the world, with a keen humour of his own, had the qualities which make a successful physician, but does not seem to have had any great scientific ability. One of his tenets—which raised the ire of Dr. Johnson—was that pulsation causes death by attrition, and that therefore, the way to prolong life is to retard pulsation. On the other hand he advocated surgical intervention in the treatment of empyema and abscess of the lung, and he held eminently sensible views on the beneficent part played by "animacules" in vegetable and animal putrefaction. He did not admit, however, that they had anything to do with the causation of disease. We hope that we may soon have another opportunity of enjoying the fruits of Dr. Kirkpatrick's researches into Dublin medical history of the eighteenth century.

## PERSONAL.

THE KING in Council has been pleased to appoint the Duke of Northumberland, Sir Hugh Bell, Bart., Miss E. M. N. Williams, M.D.Lond., D.P.H.Cantab., Mr. G. G. Butler, M.A., Mr. J. S. G. Pemberton, M.A., and Mr. John Wilson, M.P., to be members of the Senate of the University of Durham.

MR. S. E. GARDEN, F.R.C.S.I., has been elected Surgeon to the Orthopædic Hospital, Dublin.

PROFESSOR J. T. J. MORRISON presided at the recent dinner of the past and present students of the Birmingham Medical School.

MAINLY through the efforts of Dr. W. G. Aitchison Robertson, a society has been started in Edinburgh to promote the practice of cremation.

DR. DAVID D. F. MACINTYRE has been appointed assistant medical officer to Dr. Burlaw, chief medical officer to the Board of Trade at Liverpool.

THE Metropolitan Hospital will be re-opened on December 20th by the Lord Mayor of London, accompanied by the Lady Mayoress and the Sheriffs of the City of London.

THE Queen's Hospital for Children, Hackney, has received from the Duke of Newcastle a new X-ray apparatus to replace the installation furnished by the same donor some ten years ago.

SIR T. LAUDER BRUNTON has been appointed chairman of the Physiological Committee, and Professor H. R. Kenwood, M.B., D.P.H., and Professor W. J. R. Simpson, C.M.G., M.D., F.R.C.P., D.P.H., have been appointed representatives of the University of London at the Third International Congress of School Hygiene, to be held at Paris in August, 1910.

CAPTAIN J. E. CLEMENTS, I.M.S., Superintendent of the Central Gaol, Montgomery, India, was recently stabbed in the back by a Pathan prisoner, but is reported to be progressing favourably.

COLONEL T. P. WOODHOUSE, Army Medical Service, has been appointed Principal Medical Officer Scottish Command, in succession to Colonel T. M. Corker, who is proceeding to Egypt for duty.

DR. J. ROSE BRADFORD, F.R.S., Sir C. Cameron, Kt., C.B., Dr. L. C. Parkes, Dr. M. S. Pembrey, Sir F. Treves, Bt., G.C.V.O., C.B., have been re-appointed to the Army Medical Advisory Board.

DR. L. S. McMANUS, seconded by Dr. J. T. Richards, is endeavouring to arrange for the removal of the offensive inscription on the Brown Dog Memorial at Battersea, and to substitute a truthful one.

MAJOR-GENERAL LORD CHEYLESMORE, chairman of the Brompton Hospital, opened an exhibition organised by the National Association for the Prevention of Consumption, in the Chelsea Town Hall on December 7th.

A VALUABLE collection of books and other relics of the famous Dr. Joseph Priestley, the discoverer of oxygen, has been presented to the library of the University of Birmingham by Miss S. P. Wainright, one of his descendants.

MR. W. B. HARDY, M.A., F.R.S., Professor A. F. Stanley Kent, M.A., Dr. V. H. Veley, D.Sc., M.A., F.R.S., and Professor Swale Vincent, M.D., D.Sc., have been added to the panel of lecturers in physiology at London University.

DR. R. O. MOON, who is standing in the Liberal interest for East Marylebone, London, served in the Græco-Turkish War in 1897, and in 1900 was repeatedly under fire as a trooper in the Hampshire Yeomanry in the South African War.

DR. JAMES WHITEFORD, Greenock, who has completed 50 years as a medical practitioner, has been entertained in the Watt Museum Hall, Greenock, by a numerous company of his patients and friends. He was presented with an address and a cheque for £930.

DR. C. HUBERT ROBERTS, M.D., F.R.C.S., a physician to in-patients; Dr. R. D. Maxwell, M.D., F.R.C.S., a physician to out-patients; Mr. Thomas Crisp English, M.B., F.R.C.S., surgeon (non-obstetric), have been appointed to the staff of Queen Charlotte's Lying-in Hospital.

SIR GEORGE HARE PHILIPSON, M.B., the President of the College, and Mr. J. E. Gibson, M.A., have been elected as the two representatives of the Council of the College of Medicine, Newcastle-on-Tyne, to act on the Senate, as constituted under the University of Durham Act, 1908, while Dr. David Drummond and Professor Robert Howden have been appointed to represent the Academic Board of the College on the new Senate.

THE following will, it is stated, contest Parliamentary seats against their names at the coming election:—Dr. C. Addison (L.), Hoxton; Dr. W. A. Chapple (L.), Stirlingshire; Dr. G. Coates (U.), Lichfield; Sir W. J. Collins (L.), St. Pancras, West; Dr. T. Eastham (U.), Hyde; The Right Hon. Sir W. Foster (L.), Ilkeston; Dr. F. E. Fremantle (U.), Rotherhithe; Dr. A. Hillier (U.), North Hitchin, Hertfordshire; Dr. H. S. Lunn (L.), Boston; Dr. J. E. Molson (U.), Bethnal Green; Dr. R. O. Moon (R.), Marylebone East; Dr. Permewan, of Liverpool (L.), Bootle; Sir G. H. Pollard (L.), Eccles; Dr. A. R. Rainy (L.), Kilmarnock District; Dr. V. H. Rutherford (L.), Brentford.

# A CLINICAL LECTURE ON THE PROGNOSIS AND ÆTIOLOGY OF MITRAL INCOMPETENCE. (a)

By Sir JOHN F. H. BROADBENT, Bart., M.D.Oxon., F.R.C.P.Lond.,

Physician to St. Mary's Hospital, Paddington.

THE range of possibilities as regards prognosis is wider in mitral incompetence than in any other valvular affection. The incompetence may be due to a variety of causes, and inasmuch as the prognosis will to a great extent depend on the ætiology of the affection, I have selected as the title for my paper "The Prognosis and Ætiology of Mitral Incompetence."

The varieties of mitral incompetence, ætiologically, may be divided into two main groups:—

- (1) Incompetence due to actual lesion of the valves.
- (2) Incompetence resulting from dilatation of the left ventricle unattended with any lesion of the valves.

Rheumatic endocarditis is by far the commonest ætiological factor in Group I. Sometimes scarlet fever may be responsible. Pneumococcal or streptococcal infection may also set up endocarditis, but in this event the variety known as "malignant endocarditis" more commonly results and usually proves fatal.

Chronic degenerative change giving rise to some thickening and rigidity of the valves may be a cause of incompetence setting in in the later periods of life. This is of far greater importance in the case of the aortic than the mitral valve.

A large proportion of cases of mitral incompetence in which we are called upon to give a prognosis, come before us as old-established chronic valvular lesions traceable to rheumatic endocarditis. In this group our task will be a comparatively easy one. We must first proceed by the data at our command to endeavour to estimate the extent of the lesion.

*The character of the murmur and the first sound will afford important information.* If the murmur is not conducted much beyond the apex beat, is not audible in the back, and does not replace to any great extent the first sound, or if it follows the first sound at a brief but appreciable interval—i.e., is late systolic in time—the regurgitation is presumably slight in amount. If the systolic murmur replaces entirely or greatly modifies the first sound, we may infer that the lesion is severe, inasmuch as the intra-ventricular pressure is so reduced by the regurgitation through the mitral orifice that it is insufficient to make the muscular wall, as it suddenly contracts down on the contained blood, taut enough to generate a first sound.

As the work of compensation falls mainly on the right ventricle, the degree of enlargement and hypertrophy of the right ventricle will be an important guide to the severity of the mitral lesion. Enlargement of the right ventricle will cause displacement outwards and somewhat downwards of the apex beat and undue right ventricle impulse in the epigastrium, and in proportion as these are pronounced we may infer the degree of severity of the mitral lesion. The degree of accentuation of the pulmonic second sound will also afford useful information as to the increase of pressure in the pulmonary circulation.

*Symptoms.*—A very important factor in prognosis will be the readiness with which symptoms of cardiac distress are induced, or a breakdown of compensation occurs.

Many people are going about with a mitral lesion who are utterly ignorant of the fact, and lead an ordinary life, taking plenty of exercise without suffering any inconvenience. Here we shall find little appreciable evidence of compensatory changes, and it is obvious that the lesion in such cases is so slight as to be almost negligible, whatever the character of the murmur.

(a) Delivered at the Medical Graduates' College and Polyclinic.

In other cases the patient, though unconscious of any heart affection, comes to consult one for shortness of breath on going uphill or upstairs, though comfortable when taking ordinary walking exercise. In these cases one will usually find accentuation of the pulmonic second sound, and evidence of compensatory changes in the shape of hypertrophy of the right ventricle with some displacement outwards of the apex beat.

It is important in considering the prognosis of this class of cases to bear in mind the question of the reserve power of the heart. In the healthy heart there is an enormous reserve power which enables it to respond to the increased demands entailed by exertion and exercise without any symptoms or ill-effect. This reserve power is diminished if one of the valves be damaged, even if efficient compensation has taken place, in proportion to the severity of the valvular lesion, so that if the heart be over-taxed, warning symptoms, such as dyspnoea, præcordial pain, etc., set in, and if the undue exertion be persisted in, breakdown of compensation will result. In these cases it will be necessary to lay down strict rules as to the amount and nature of the exercise allowed, and to explain to the patient that these symptoms are in the nature of a warning to desist at once from the exertion which induces them.

In regard to prognosis in cases of complete breakdown of compensation in which enlargement of the liver, dropsy, etc., are present, much will depend on whether the breakdown has been induced by undue exertion, or an attack of bronchitis, or has occurred while the patient has been taking all possible precautions. In the former event it is remarkable how time and again they will respond to suitable treatment by rest and the administration of purgatives and digitalis. In the latter the prognosis is necessarily unfavourable, the more so as the onset of symptoms is likely to be due to commencing degenerative change in the cardiac muscle.

A danger to be apprehended in the years to come in cases of mitral incompetence that come under our notice shortly after an attack of endocarditis, which should make our prognosis guarded even in apparently favourable cases, is the possibility of the onset in the future of mitral stenosis from cicatricial contraction of the damaged valves. My impression is, that in many cases the patient who has had mitral incompetence for some years, it may be, only comes up for medical advice when mitral stenosis has set in and symptoms attributable to that affection begin to present themselves.

## "MITRAL INCOMPETENCE DUE TO DILATATION OF THE MITRAL ORIFICE."

In dealing with the question of prognosis in mitral incompetence due to dilatation of the left ventricle, without actual lesion of the valves, the ætiological factors are of extreme importance, and are many and varied.

When during an attack of rheumatism a systolic murmur develops at the apex indicative of mitral incompetence, it is often a difficult matter to decide whether this is due to damage to the valves from endocarditis or is the result of dilatation of the left ventricle.

If the murmur is musical in character or changes in quality while the patient is under observation, we may be fairly certain that it is the result of actual lesion to the valves. If there is little evidence of dilatation of the ventricle, only slight displacement of

the apex beat, and no great increase in the area of cardiac dullness, and the murmur is soft and blowing in character, it may be necessary to wait for some weeks after the subsidence of the attack before we can decide with certainty as to its nature.

If after the subsidence of an attack of rheumatic pericarditis in a child we find that the cavities of the heart, both right and left, remain greatly dilated, and notice that there are marked symptoms of cardiac distress such as rapid respiration and pulse, orthopnoea, and perhaps enlargement of the liver, and on auscultation at the apex we hear a loud, blowing systolic murmur, we may perhaps be inclined to attribute these in part to a lesion of the mitral valve. Such may, or may not, be present, but is of minor importance, as in these cases the extreme dilatation and accompanying symptoms are the consequence, not of a valvular lesion, but of damage to the myocardium inflicted by the toxins of the rheumatic micro-organisms. Microscopically, in fatal cases we find evidence of this damage in the loss of striation of the cardiac muscle, and granular and fatty degeneration of the muscle fibres, and the areas of small, rounded infiltration which scattered throughout.

Inasmuch as the right ventricle is usually affected in the same degree as the left, and, being thinner-walled, dilates even more readily, there is no compensatory mechanism available to counteract the effects of the mitral incompetence, and in severe or prolonged attacks, enlargement of the liver, distressing dyspnoea, and dropsy may set in. If the patient survives the attack, and the heart does not recover from the dilatation, but remains permanently enlarged, with a loud, blowing, systolic murmur at the apex heard through at the back, even though some hypertrophy set in, the prognosis as regards efficiency of compensation or prolonged life is necessarily unfavourable.

There are many causes, other than rheumatism, of dilatation of the left ventricle leading to mitral incompetence, and I now propose to deal with some of these.

In *Graves' disease* a mitral systolic murmur is frequently present, associated with a varying degree of cardiac dilatation. In a small percentage of cases the dilatation may become extreme and prove fatal. In the majority of cases recovery takes place when the *Graves' syndrome* subsides. In a case of a lady, *æt.* 40, recently under my care, in whom *Graves' disease* had developed somewhat suddenly, the heart was enormously dilated, the apex beat being in the sixth space in the axillary line. A loud, blowing, systolic murmur was present, conducted to the axilla and heard in the back, and there was dyspnoea with enlargement of the liver and slight dropsy. After a month in bed, and treatment with digitalis and bromides, the dropsy and enlargement of the liver subsided, but there was still tachycardia and breathlessness, and the cavities of the heart remained much the same. Six months later the tachycardia had subsided, the swelling of the thyroid was greatly reduced, and the apex beat had come into the nipple line, but a loud systolic murmur was still present. A year later the systolic murmur had entirely disappeared, there was only slight breathlessness on exertion, and she had put on 2 stone in weight. She now enjoys excellent health.

The exact cause of the dilatation in *Graves' disease* is not altogether clear. The rapid action of the heart, so constantly present, must tend to exhaust the muscle, and might be a predisposing cause; but the relaxed condition of the vessels, which is so remarkable a feature, will, on the other hand, relieve the heart of work to a great extent, and I think we must attribute the dilatation in part, at any rate, to the toxic action of the excessive thyroid secretion on the cardiac muscle.

*Chronic alcoholism* is not infrequently a cause of mitral incompetence in later life. As the dilatation of the left ventricle, which is responsible for the incompetence, is usually due to degenerative changes in the cardiac muscle, the prognosis is necessarily unfavourable. The regurgitation may, however, be only slight in amount, and the immediate cause of danger be cirrhosis of the liver or multiple neuritis. When

the regurgitation is considerable, rest and suitable treatment may cause a marked temporary improvement in the symptoms, and a certain *modus vivendi* be established if the patient can have every care and attention. On return to ordinary life, however, a relapse usually occurs, even if the patient can be induced to give up alcohol altogether. In hospital patients, consequently, the prognosis is more unfavourable than in the wealthier classes.

Some two years ago I was called to see a lady of about 50 years of age in whose case the outbreak of delirium tremens had made manifest for the first time the fact that she was a secret drinker. The pulse was 120, the heart apex beat was in the sixth space in the mid-axillary line, and a loud, blowing, systolic murmur was present; the liver was enlarged, and there was some oedema of the lungs. She improved gradually, and in two months' time was able to get about again and take short walks on the level. The pulse rate was 84, and the heart apex had come into the anterior axillary line, and though the murmur was present it was much less pronounced. As a result of over-exertion while on a holiday, the heart again broke down, and rest in bed for some weeks was necessitated before the working balance was again restored. By dint of great care this has been maintained, but a loud systolic murmur is still present, and there is practically no reserve power available that will allow of undue exertion without causing a relapse.

The degree in which the cardiac muscle is affected is necessarily an important point in prognosis, and this can only be estimated by the response to treatment in each individual case. Beer is, I think, more injurious than spirits in that it has a greater tendency to produce fatty degeneration of the cardiac muscle. It is remarkable how long secret drinking of spirits by the female sex may go on before any evidence of cardiac breakdown occurs. Tachycardia is of common occurrence and may persist for years. In two cases I saw from time to time for several years I was inclined to make an erroneous diagnosis of *Graves' disease* on the strength of the tachycardia and tremor, as, of course, the utmost these ladies admitted they took in the way of alcohol, was a glass of claret for dinner, and it might be occasionally a little brandy for a "faint feeling."

*Slight degrees of mitral incompetence unattended by symptoms.*—In young and apparently healthy adults a soft systolic mitral murmur may be present, not traceable to rheumatism or any recent illness, and giving rise to no symptom of any kind, so that it may only be discovered more or less by chance.

To give three instances which have come under my notice within the last three months:—

CASE 1.—W. H., a medical student, in the best of health and able to take active exercise without any symptoms of distress, came to consult me because he was thinking of going into the Army Medical Service, and he wished to be examined to see that he was medically fit. On examining the heart, I found a soft, blowing systolic murmur at the apex. There was some enlargement of the left ventricle, the apex beat being just outside the nipple line in the fifth space. It was somewhat forcible and thrusting in character. The blood pressure was rather high, 160 mm. by the Riva Rocci instrument. The urine was normal. There was no history of rheumatism at any time.

In searching for a possible cause of the onset of the mitral incompetence, I ascertained that six months previously he had a sharp attack of influenza, and that ten days after he was convalescent from this, he had gone for a 20 mile run with the harriers. Though not distressed at the time, he had not felt up to the mark or equal to much exertion for some time after, and I take it that the violent exercise so soon after his illness may have induced dilatation of the left ventricle, and that the mitral incompetence dated from this. The high arterial tension would also be an important predisposing cause.

CASE 2.—A man, *æt.* 33, came to consult me with the history that he had been working hard for some time in a close, badly-ventilated office, and felt generally run down in health. He found that he could not take

active exercise and play golf as he used to every week-end without getting short of breath and very soon tired. The pulse was regular and of low tension. On examining the heart, the apex beat was scarcely palpable in the fifth space just inside the nipple line, and a blowing systolic murmur was audible over a limited area. There was no appreciable increase in the area of cardiac dullness. He was somewhat anæmic, but well nourished. I advised him to take a complete holiday for some weeks in a bracing climate, and take moderate exercise, strictly limited in amount at first, but gradually increasing in duration each day till he found he could walk uphill or play golf without any dyspnoea. He improved rapidly, and two months later I heard from his doctor that he was in excellent health, and that the murmur was then only present after exertion.

CASE 3.—The third case was that of a man, æt. 27, who had been doing arduous work as a mining engineer in South Africa, and had recently recovered from a severe head injury which necessitated trephining. When I saw him on his arrival in England on July 8th, he was poorly nourished, and complained of headache and of feeling tired on slight exertion. A soft systolic mitral murmur was audible at the apex, which was in the fifth space just inside the nipple line. There was no appreciable increase in the area of cardiac dullness. The pulse was regular 74, and of low tension.

After a holiday of two months at a bracing seaside health resort, he had put on two stone in weight and said he felt in excellent health. The murmur was still present, but scarcely audible except after exertion. He then went off on a shooting expedition abroad, and I heard that he was able to do a long day's tramp without feeling fatigue or ill effect.

In these last two cases there was no evidence of any appreciable dilatation of the left ventricle, on percussion or any displacement of the apex beat, nor were the cardiac symptoms in any way pronounced.

In seeking for an explanation of the mitral murmur in these and other similar cases, we must bear in mind that the mitral orifice is not like the aortic orifice, a firm, unyielding cartilaginous ring, but is a fibrous structure surrounded by a band of circular muscle fibres, which by their contraction in systole play an important part in maintaining the efficient closure of the valves. Further, the papillary muscles attached by the chordæ tendinæ to the margin of the valves are also factors in the mechanism which secures accurate apposition of the valvular curtains by preventing their undue displacement upwards by the strain to which they are subjected during the ventricular systole. It is thus essential for the efficient closure of the mitral orifice that the muscular ring surrounding it and the muscoli papillares controlling the valves should be in good working order.

It is readily conceivable, therefore, that impairment of tonicity of this band of circular muscle fibres and consequent imperfect contraction during systole of the ventricle may render the valves incompetent from dilatation of the ring to which they are attached. Similarly, impairment of tonicity of the ventricle, affecting also the muscoli papillares so that they do not con-also the muscoli papillares so that they do not con-also the muscoli papillares so that they do not con-also the muscoli papillares so that they do not con-also the muscoli papillares so that they do not con-also the muscoli papillares so that they do not con-

It is to one or both of these causes combined that I attribute the mitral incompetence in the two last-mentioned cases from loss of general and cardiac muscular tone, and I should expect that in a short time, given favourable circumstances, the heart would recover its tone and the murmurs entirely disappear. To the same causation we may attribute the transitory mitral murmurs which may make their appearance during the course of acute febrile disorders, the apical murmurs in anæmia, and the mitral systolic murmurs met with in some cases of chorea and slighter degrees of rheumatism in children, which eventually disappear entirely.

There are many other varieties of mitral incompetence, such as that due to prolonged high arterial tension, to chronic degenerative change in the valves, and that secondary to disease of the aortic valves, and so on, which time will not permit me to discuss, as

I fear I have already overstepped the limit of that allotted to me.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by D'Arcy Power, F.R.C.S., Surgeon to St. Bartholomew's Hospital. Subject "Varicocele."

## ORIGINAL PAPERS.

### SOME REMARKS ON THE PERITONEUM AND PERITONITIS. (a)

BY E. ROCK CARLING, M.B.LOND., B.S.,  
F.R.C.S.ENG.,

Dean of the Westminster Hospital Medical School; Assistant Surgeon, Westminster Hospital; Senior Assistant Surgeon, Seamen's Hospital, Greenwich.

(Concluded from page 608.)

AGAIN, an appendix, perforated and sloughing may have to be left behind, against the will of the operator, if it be so firmly embedded in the walls of the cæcum, or so obscured by dense adhesion of surrounding gut, that its removal would endanger the vitality of the intestinal walls adjacent. Of course, the abdominal contents will submit tamely to considerable violence, and one knows quite well that the mere formation of a fæcal fistula is often of comparatively little moment; one must judge by the state of the tissues what risks to run, remembering that the risk to choose, should be rather that of damaging the peritoneum or gut, when one is sure of being able to repair it, than the risk of leaving behind an inexhaustible source of renewed infection. One may find a pelvis full of pus only imperfectly isolated, and, operating through this area, remove "tubes" full of bursting with pus, perhaps even with pus exuding from their abdominal ostia, and yet scarcely endanger the general peritoneal cavity. But if the removal of "tubes," full of semi-solid or caseous purulent detritus, which proves sterile on inoculation, necessitates the separation of numerous adhesions of the overlying loops of intestines to one another and to the parietes, then, even if the adhesions be of old standing, all the resources of surgery may be taxed to their utmost to avoid a fatal infection of the whole cavity; so easily do virulent organism find their way out through the breaches of continuity left by separation of adhesions even where every care has been exercised. Turbid fluid is not necessarily a danger, on the contrary it is probably the chief hope for the patient; fluid definitely purulent, has probably done all its protective work, and will be better outside the abdomen; where pus is universal, complete irrigation would perhaps be justifiable could it be done without undue disturbance of the contents, and without mechanical damage to the surfaces manipulated. At the recent congress (38) of the German Surgical Society a majority of surgeons were, indeed, in favour of irrigation in the treatment of generalised peritonitis. Some went so far as to recommend complete breaking down of all recent adhesions (36), (37), (38), (39) to ensure thorough washing out. My personal opinion is, that upon the operating table it is impossible to wash out the whole, or anything like the whole of the purulent contents; moreover, in my experience, anything but the most perfunctory irrigation is attended with danger to the sacred peritoneal surfaces. Attempts have been made by the introduction of long tubes specially adapted to reach distant parts of the cavity, to maintain continuous or intermittent irrigation. (40)

Fortunately, however, this is not necessary, Murphy (14), (41) has introduced continuous infusion of saline solution by the rectum, and has thereby contributed enormously to the progress of surgery, in the treat-

(a) A Paper read before the Cork Medical and Surgical Society, October, 1909.

ment of acute infections of the peritoneum. By introducing saline fluid into the rectum under pressure just sufficient to ensure its running in at about the rate of a pint an hour, enormous quantities can be absorbed. Not only are the peripheral vessels filled, the vascular tone re-established and the heart thus revived, but it is possible to promote exudation into the peritoneal cavity over the whole area, and by the adoption of the "Fowler" position, *i.e.*, with the body inclined at an angle of 70 degrees to the horizontal, together with the provision of a means of escape for the fluid at a lower level than the dome of the diaphragm, it is possible to ensure a thorough flushing of the whole cavity towards the exterior. For a few hours after drainage has been established, it is possible to get such a current of fluid flowing across the infected area, towards the dressings, that the mattress may be soaked (if no mackintosh be in place) and the water drip on to the floor underneath the bed, without the escape of one drop from the anus. If for any reason the rectum cannot be employed—though the tube is tolerated extremely well—the fluid may be introduced through large needles into the subcutaneous tissues of the thighs, and will be absorbed almost at the same rate; this method, however, has the disadvantage that there is often, subsequently, a great deal of pain about the site of infusion.

Nor does the employment of the rectal infusion method, or proctoclysis, for which special apparatus has been devised, (42), (43) preclude the employment of the various means for evacuating the bowels. In the first place the most efficient time for proctoclysis is the 10 or 12 hours immediately succeeding operation, and, in the second, if the apparatus be properly arranged, the passage of flatus by the tube itself, is permitted without difficulty; when once free action of the bowels is established, saline infusion may be stopped or intermitted. In the ordinary way, half a grain or one grain of calomel, repeated hourly, beginning an hour or two after the operation, is the most efficient aperient; if the calomel, as is often the case, produces reflex vomiting, small doses of salts, also repeated hourly, make an efficient substitute. When it is thought desirable to use strychnine at four-hourly intervals, subsequently to operation it may be suitably combined with physostigmine sulphate or Eserine salicylate (44), (45) one-fortieth to one-eightieth of a grain. Others have used castor-oil (46) injected into a coil of small intestine at the end of the operation, and the injection of magnesium sulphate through an enterotomy wound is commonly practised. (47) Spartein sulphate and digalen have also been used.

On the question of enterotomy there is considerable difference of opinion. Personally, I use it in cases in which the contents of partially paralysed gut are chiefly fluid, and especially when there is regurgitation of intestinal contents into the stomach, or when the vomit is foul. A single incision suffices, when Moynihan's tube is used, to empty five or six feet of gut; it is remarkable how intestine which has distended rapidly during the course of an operation, in which the walls seem very thin, or on the other hand, sodden, will recover and contract when the contents are evacuated. The procedure can be carried out with a minimum of risk of soiling the wound area. (48), (49) Lavage of the stomach is properly employed in these cases and has undoubted advantages.

Sprengel, who originally advocated enterostomy has now abandoned it except in special cases, and that attitude is probably correct. It is an important and valuable method, but not one for general application as a means of treating the peritonitis. (50)

Krogius (39) has advocated the formation of a fistula by Witzel's method, in the presence of meteorism. It has even been proposed to treat persistent vomiting by gastrostomy (51) combined with enterostomy. Noetzel thinks enterostomy useless in cases that won't get well without it.

The question of drainage is a difficult one. When Surgical Registrar, I was much struck with the superior results obtained in cases of appendix abscess and peri-

tonitis by those surgeons who left a large wound widely open and packed with gauze, as compared with those who attempted to suture the wound (52) up to and round the drainage tube. Yet the pendulum has swung back so much that some surgeons now advocate total suture of the abdomen even in diffuse suppurative peritonitis, and many aim at "restoring the intra-abdominal pressure," which is, of course, the efficient agent in securing escape of fluid up drainage tubes from the pelvis and other deep-lying parts. Sprengel (53) stated that he had often seen necrosis of fascia when septic cases were sewn up; this might be anticipated.

Tube drainage, however, applied to the pelvis, the flanks, or even posteriorly, cannot remain effective for more than a few hours. It is of service mainly in facilitating the diversion of the peritoneal current from its normal direction towards the diaphragm: a diversion also assisted by the "Fowler" or semi-upright position. Drainage by tampon undoubtedly has the disadvantage that it is apt to hinder peristalsis, and when employed extensively in the pelvis may contribute seriously to the persistence of constipation.

My own practice is to drain the pelvis when it has contained much pus, for twenty-four hours, by glass tube with a "wick" of ribbon gauze in the lumen. If there has been pus in the flanks they are drained by short, stout rubber tubes; that on the right side drains the subhepatic space if necessary, but these tubes are removed within forty-eight hours, those in the flanks being replaced by gauze, that in the pelvis by a rubber tube of smaller calibre, which is rapidly shortened day by day. Where the focus of infection cannot be removed entirely, or where its removal leaves behind much densely infiltrated or sloughing tissue, or where a definite abscess cavity has been opened, the best means, in my opinion, is a split india-rubber tube filled with iodoform gauze, or gauze surrounded by rubber-dam, the "cigarette" drain. It can be disposed so as to leave the gauze surface in contact with the sloughy area and to protect "new" intestine from contact with the raw area. Tamponade is used where there is much bleeding from granulating surfaces, or detached adhesions, or where the demands of time preclude a partial suture of the abdominal wound. Recognising the difficulty of maintaining persistent drainage some have tried to adopt specially shaped glass tubes. For example, Janssen, (54) uses a bunch of globe-ended glass tubes or "Kügeldrains," which he surrounds with a sheet of gauze, but it is very doubtful if this manoeuvre really postpones the agglutination of intestinal coils and omentum which so quickly invalidates all ordinary attempts at drainage. When gauze wicks or tampons are employed, it has been suggested that the outer end ought to be lower than the inner; (52) this is unnecessary, because the outer dressing is in mechanical contact and sub-serves any syphon-purpose that may be involved. Gauze tampons should not be removed as a whole for forty-eight or seventy-two hours, as the damaged gut to which they may be applied is apt to be very adherent up till that time. The envelope of rubber-dam greatly facilitates removal.

The question of adhesions is one that exercises the minds of all surgeons. After the excision of a perforated appendix in an abdomen not yet extensively infected—so far as inspection goes—but at the same time not shut off by adhesions, one expects nowadays to secure a favourable course in the after-treatment. Now and again, however, especially I think when the pneumococcus is the infective, or one of the infective agents, intestinal obstruction sets in, and on re-opening the abdomen there may be found firm and continuous adhesions of coils of gut in the neighbourhood, acutely angulated, and all attempts at unloosening them may result in tearing loose the peritoneal coat—that dread danger—rather than in separation of the very recent, hardly-yet organised, tissue. If one can distinguish for certain a coil well above that involved, it is probably best to anastomose it to intestine below, in spite of the presence of sepsis, rather than attempt

extensive separation. Enterostomy may be justified. Everyone has been surprised at the remarkable way in which adhesions will, at times, disappear. An abdomen in which, at the time of an urgency operation it seemed impossible to find one's way in any direction, when re-opened later may disclose no visible adhesions. (56) On the other hand, after a comparatively simple operation where no adverse symptom hinders the immediate progress of the case, a great deal of trouble may arise subsequently by reason of slight or extensive adhesions. Mere attachment of a tag of omentum to the abdominal scar may lead to incapacitating discomfort in a neurotically-inclined subject. A slender band of adhesions crossing the colon may suffice to produce chronic intestinal obstruction with attacks of very severe colicky pain. It is more common, however, to find several coils of small intestine united along each arm of every loop by broad sheets of thin fibrous tissue, comparatively easy to separate and tie off as a rule, but here and there perhaps constricting the gut in a manner very difficult to relieve. It seems almost impossible to divine in which cases adhesions are to be expected, and almost equally difficult to prevent their formation. It is probable that adhesions form, as a rule, only when too denuded or abraded surfaces come in contact; that a smooth undamaged peritoneal surface does not adhere to a raw area with which it comes in contact casually, although it may, of course, do so if it remain in close apposition.

But even two raw surfaces do not necessarily adhere: Von Dembrowski (57) scrubbed the peritoneum of a dog with a hard tooth-brush, without producing adhesion; foreign bodies, such as tinctacks (58) or pins (59) will sometimes simply be encysted, at others may produce extensive adhesions. Swabs (60) will sometimes remain for long periods without giving trouble. In a recent instance, fluid from a case of ascites, obtained by tapping, was found to contain a quantity of carbon which had been administered as charcoal. The puncture of the gut produced no adverse symptoms.

The peritoneum possesses remarkable powers of encystment. After rupture of a gastric ulcer, or of the small intestine, vegetable particles (61), (62) may be found encysted, and even pedunculated upon the serous surface. Similarly with cancer cells or with droplets of vaseline (63) introduced experimentally.

Many experiments have been made to devise some means of preventing the formation of adhesions. Sterile oil, (64), (65), (66) gelatine, lanoline, paraffin, gum-arabic, have all been tried and none have any effect. The more irritating fatty-acids, such as cottonseed or linseed oil, or palmitic acid, in fact, produce great plastic reaction and are a direct menace to life.

When sterile oil (67) is used 10 to 50 c.cm. are poured into the belly at the end of operation. Some surgeons think that a quantity of saline fluid left in the abdomen serves a purpose in preventing adhesions; this at least is an innocuous method. All we can do at present is to avoid damage to, or dessication (68) of, the exposed peritoneum; to avoid the use of chemical irritants in the abdominal cavity; to cover exposed areas wherever possible, by suture or omental grafts (69) or even by some such medium as cargile membrane. Very important is the early promotion of intestinal movements. To this end strychnine and physostigmine may certainly be addressed and in several cases I have found massage of value in dispelling symptoms presumably attributable to adhesions.

As to the use of sera and vaccines, I can only say that in acute cases, sera have little if any influence, and the preparation of vaccines requires too long to permit their use in the urgent stages; but for clearing up persistent sinuses after local peritonitis there is no doubt that vaccines, properly prepared in accordance with the actual bacterial content of the discharge, have a field of usefulness.

A knowledge of the natural means of defence of the peritoneum and a recognition of the points at which its armour is weak, enable us to interfere with

discretion, and to render aid diplomatically. Before anything was known of the mechanism of defence, surgeons avoided meddling with the peritoneum as they avoided the devil; now we avoid undue intervention on the principle of letting well alone. We know exactly how we can aid the natural powers of resistance, and we act with promptitude, with the least possible expenditure of time at the table, and with severe restrictions. One has, however, always to be keeping oneself up to the proper earnestness in prosecuting the non-operative after-treatment. It is not enough to put a pillow under the patient's shoulders and call it the "Fowler" position. The body should be inclined at from 60 to 80 degrees to the bed, and that position requires some ingenuity on the part of the nurse, for its maintenance. Merely to put a syringe of two of saline into the rectum is not carrying out proctoclysis. Things are not right unless at least one pint is flowing steadily into the rectum per hour, hour after hour, without discomfort to the patient. Whatever aperient is employed must be followed up steadily until it succeeds. It is difficult to impress upon house surgeons and ward sisters that the critical time is not that spent in the theatre, but the 24 hours next following. Above all, time is the important factor; the bacteriologist may have to sit up all night to make his vaccine, but unless he does so, he may as well not make it at all in some cases. A delay of an hour or two on the part of the surgeon in doing the operation may rob a patient of a good chance of life.

It is, of course, to the same protective power enjoyed by the peritoneum that we owe the impunity with which we now perform routine anastomoses and other intra-abdominal operations. No surgeon who is also a bacteriologist thinks that his anastomoses, even when performed by crushing or by special methods that profess to avoid opening the lumen to daylight, are accomplished without infecting the peritoneum. He knows, however, that unless he is unfortunate enough to let loose a lurking devil, such as the *b. aerogenes capsulatus*, he can rely on the peritoneum to deal with all organisms that escape. The experiences of military surgery, and *a priori* considerations, suggest the advisability of very careful attention to the state of the intestines, both as regards food and as regards the bacterial content, before a deliberate operation. It might be advisable to displace the normal but potentially virulent organisms by a course of lactic acid bacilli which are not pathogenic.

It is unnecessary to say that the power of the peritoneum to take care of itself does not in any way absolve us from the duty of protecting it from insult, but it is satisfactory to feel that in a case, for example, of gangrenous gut in a hernial sac, the abdomen may be opened with impunity and a reasonable chance of performing an anastomosis through an adequate opening be obtained without fear of setting up a fatal peritonitis.

The physiology I have recapitulated is not very new; the practical measures described are in common practice, and most of the observations are trite, to say the least of it, but I trust you will agree with me that no harm is done by an occasional recitation of the faith that is in us.

## THE EARLY DIAGNOSIS OF SUPPURATIONS OF THE MASTOID.

By A. JANSEN, M.D.,  
Of Berlin.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

So soon as suppurations of the middle ear pass beyond the limits of the cavity of the tympanum, into the region of the mastoid, the character of the mischief becomes changed. It is, therefore, important to recognise the passing of the inflammation from the one part to the other early. Unfortunately, the complication often runs on for some time without any symptom, so that a recognition of it is impossible. Sooner or later, however, the inflammation of the middle ear undergoes changes due to the complication. The aetiological factor, and constitutional diseases, along with the anatomical structure of the mastoid are of importance. Although in acute otitis media the tympanic cavity towards the "antrum" becomes closed frequently, from adhesions of the swollen mucous membrane, in a number of severe cases the mucous surface in the antrum becomes inflamed also. With the healing of the inflammation in the tympanic cavity that in the antrum also subsides spontaneously. So soon as the mastoid itself, however, becomes diseased, the condition becomes worse as regards spontaneous healing, and when suppuration has actually occurred, spontaneous recovery takes place no longer.

The development of suppuration in the mastoid and its spread depend in the first instance on the form of this bony part, the structure of which is exceedingly complicated. The mastoid process may be very small, or it may develop to a large size in all dimensions. It may be composed of compact ivory-like bone, or of a softer, spongy bony substance. The antrum also varies very much, usually approaching the size of a pea, frequently smaller, it may be so small as to appear as only a small appendage to the tympanic cavity. These varied conditions of the antrum and bones are directly decisive for the kind and extent of the suppuration in the mastoid. Suppuration in a small, high lying antrum is much more favourable for spontaneous recovery, and especially when the bones are sclerosed than suppuration in a large antrum with deep recesses in which stagnation is always present. Suppurations of the middle ear that are complicated by disease of the mastoid process, have an influence on the secretion from the tympanum, both in regard to quantity and appearance. An unusually large quantity of pus, and a preponderance of pure pus in it, are an early and

sure sign of suppuration of the mastoid with free outflow from the tympanic cavity, frequently long before any other signs are present. In chronic cases the foul smell that persists in spite of careful cleansing as well as the mucoid character of the discharge, point to decomposition in the antrum and mastoid, and they in combination with large quantities of lamellae of cholesteotoma, form certain indications of suppuration in the mastoid. On examining the tympanum we see in the unceasing flow of pus through the perforation, a very early symptom of retention in the antrum and mastoid. When we see this unceasing welling out of the discharge at a time when the secretion in the regular course of the otitis media should be less it is so much the more characteristic, as with moderate outflow of pus the inflammatory changes in and about the mastoid may undergo great extension without any other symptoms being present.

The more circumscribed swelling and depression in the neighbourhood above and behind the tympanum, often indicates at the commencement only severe participation of the cavity of the tympanum, of the antrum and mastoid. These affections may be recovered from without operation. When the posterior or posterior and upper wall of the auditory canal is changed so that the lumen is contracted to a mere slit, it is to be taken as a sign of grave disease of the antrum and mastoid. In chronic suppuration, the diagnostic value of depression and swelling of the posterior and upper part of the auditory canal is much greater still. In cases with a bad outlook, it is frequently the only visible sign of a serious complication.

Swelling, redness and tenderness on pressure may appear at any stage of the affection, but they do not by any means indicate the presence of a purulent disease of bone that cannot become absorbed. They show that the interior of the bone is implicated in the disease of the middle ear with hyperæmia and œdema of the bone coverings, and serous effusion into the cavities. If the conditions are favourable these symptoms generally subside quickly. Subperiosteal suppurations also occasionally become absorbed. When the periostitis of the mastoid returns again after it has once disappeared however, or if it persists in spite of appropriate treatment, we must look on it as a sign of an inflammatory process in the mastoid in which spontaneous recovery is out of the question. In chronic inflammations of the middle ear, periostitis of the mastoid process is always a certain indication of purulent disease in the interior of the bone that will not get well spontaneously, and is an absolute indication for operation. Whilst phlegmonous periostitis would appear to be an affection that threatens great danger, as a matter of fact, the danger to life is far less than with suppuration in the interior without external indications of it, where a very hard bony layer prevents the pus escaping outwardly and forces it inwards.

As soon as suppuration in the mastoid is diagnosed, no time should be lost in waiting, considering the disastrous consequences of the pus being driven into the deeper parts.

Before the bony surface of the mastoid shows any marked changes, the pus finds its way out in some places. It not infrequently breaks out from the large cells at the base of the process, and leads to phlegmonous inflammation of the soft

parts. The bursting through of pus on the median surface of the mastoid below the lateral muscles of the neck is, at first, unobserved and leads to a firm, deep-reaching phlegmonous infiltration in the neck below the bone, when the mastoid process is sclerosed and the pus is forced into the posterior fossa of the skull, and spreads into the sulcus sigmoideus, it sometimes lies near the surface at the posterior border of the mastoid, where the bone covering it is frequently very thin and firm, this cause easily sets up otitis and peritonsillitis behind the process which may, as far as external appearances go, be quite intact.

In suppurations of the mastoid, one-sided headache is an important and early symptom, sometimes it is the only one. In general the pains in the head are the most severe when there is a thick layer of granulation in the antrum or mastoid and suppuration has taken place. It cannot be sufficiently emphasised that just those cases in which all symptoms are absent, except the headache, are to be looked upon as the most serious, and where the question as to operation has to be decided at once.

When there is much fever in adults or grown-up children, the case is generally one of serious infection, or one of not uncomplicated suppuration of the antrum and mastoid.

Damage to the power of hearing is a necessary accompaniment to acute inflammation of the middle ear. When, however, the loss of hearing continues after the affection has subsided, it is either because the labyrinth has become implicated, or that the swelling in the Eustachian has not subsided. When the swelling of the mucous membrane of the Eustachian tube has not subsided after some weeks, the cause is generally some collection in the antrum and mastoid.

Paralysis of the facial nerve in acute inflammation of the middle ear is of no value as regards a diagnosis of suppuration. Paralysis coming on late may rather awaken a suspicion of suppuration in the mastoid. In chronic suppurations, on the other hand, the onset of paralysis of the facial nerve is of much more diagnostic value as regards the presence of serious disease of the bones of the mastoid process.

### "SCARLET FEVER FROM COWS."

By G. DE GORREQUER GRIFFITH,

Physician to the Hospital for Women and Children, Westminster.

UNDER the above heading, in your number of November 10th, 1909, is the following:—

"The London County Council have issued a report by their Medical Officer submitting a report by Dr. W. H. Hamer and Dr. T. Henry Jones on an outbreak of scarlet fever last June in London and Surrey, and a bacteriological report by Dr. Mervyn Gordon.

"According to Sir Shirley Murphy's report, the outbreak affected upwards of 400 persons, who consumed milk obtained from a particular milk company. He discusses the two hypotheses of human or bovine origin for the fever. The former hypothesis is dismissed, as careful inquiry failed to yield any evidence of a human source of infection.

"On the question of bovine infection, the report says:—'Under similar circumstances Sir William Power, in 1882, when investigating an outbreak of scarlet fever in certain London districts, made the suggestion that inasmuch as "there is one sort of

relation between scarlatina and accidents of the puerperal state, another sort of relation becomes comparatively easy of belief," in fact, that "if scarlatina in man have other animal source than human source, it may be that one such source is the cow that has recently calved, a cow either not at all ill (except for her parturition), or not so obviously ill as to prevent her milk being used for human consumption." The suggestion thus tentatively made in 1882 at once assumed large importance upon the demonstration by Sir William Power, in 1885, of the bovine origin of scarlet fever occurring in persons consuming milk from a Hendon farm, the cows at which were affected with an eruption of the teats and udder. A similar development of scarlet fever in man, associated with the consumption of the milk of similarly affected newly-calved cows, has been observed in a number of instances since that date. In London, in 1892, and again in 1894 and in 1902, considerable prevalences of scarlet fever due to infected milk were strongly suspected to have been originally of bovine origin. In the present instance a like possibility was necessarily entertained, and it has been found possible by study of the farm operations, in minute detail, to show that just at the time when the milk first began to show infectious property, there was added to it the milk of three recently calved cows, the calf of one of which had died after being suckled by the cow for four or five days. These circumstances, together with the fact that the three cows mentioned, and other cows at the farm, showed at the time of the inquiry appearances upon their teats and udders suggestive of Hendon disease, render it probable that a morbid condition of the cow was responsible for the subsequent human illness.'"

It would seem that scarlet fever may be originated *de novo* at the puerperal period, or, rather, I would say, that symptoms identical with scarlet fever, and not to be differentiated therefrom, may declare themselves.

These latter are hardly originated from scarlet fever, if we accept that ailment as contracted from a previously existing case, or something, or someone that has been in contact with one. This we might call true scarlet fever.

Years ago, Dr. Barnes and Dr. Braxton Hicks wrote about the facility with which puerperal patients became the subjects of scarlet fever, and it was considered the *bête noir* of midwifery.

In 1875, in a paper which I read at the Obstetrical Society, I showed that many cases were not scarlet fever at all, *i.e.*, that affection contracted from a previously existing case of scarlet fever or something infected by that disease, but were the outward and visible signs of the inward and invisible poison generated by or in the patient from something in herself, or from a poison other than scarlet fever, to which the patient was subjected at the parturient time, or previous to it, that the symptoms were those of blood-poisoning, or as is now said—toxæmia.

Sir James Paget noted that after some of his operations the patients were attacked with scarlet fever, and I wrote to him and pointed out that the symptoms—exactly like those of scarlet fever—were not scarlet fever at all, but evidence of—to use the present-day expression—sepsis, attacking the wounds; and Sir James, to whom I was personally known, courteously thanked me.

Does it not seem likely that the cows in the

cases referred to in the extract at the head of this note may have been the subjects of puerperal septicæmia, and that the secretion of those cows, when imbibed by the human being, and poisoning that person, produced those symptoms which we are in the habit of calling scarlet fever?

It would be of great interest to me as bearing on this question to know the veterinary surgeon's report on the local and general conditions of the puerperal cows, just as if they were human animals, that is, the general conditions existing at the same time as the eruption on the teats and udders appeared. If the human scarlet fever have a particular germ, it would likewise be of interest to know if that germ were found in the milk or in the blood of the cow, or in the teats and udder eruption; and also if the germ had been found in the calf which died?

In a future article, I will mention the puerperal case which occurred in 1875 that first made me see, that, at least many of the cases of "puerperal scarlet fever" were not that affection at all, but were, in reality cases of puerperal septicæmia, either autogenetic or heterogenetic.

Dr. David Walsh some years ago dealt with the above and other symptomatic rashes, which he regarded as the result of the excretion or attempted excretion of an irritant by the skin. In the particular case of a "scarlatinal" rash connected with milk, the specific irritant might well be a toxin elaborated either in the milk or in the alimentary canal of the patient. The minutely punctate redness of the eruption at its onset certainly suggest a general inflammatory resistance of cutaneous glands. If we are to connect the scarlatinal rash in this instance with milk as the infecting agent, it seems impossible to avoid the conclusion that the excretory function of the skin is involved therein. Much the same line of reasoning applies to the "scarlatinal" rash following surgical operations. Some drugs, such as copaiba, may act similarly. (a) In all cases where the skin is affected symptomatically, Dr. Walsh points out that other excretory organs may be, and usually are, more or less affected.

## OPERATING THEATRES.

### GUY'S HOSPITAL.

**OPERATION ON BADLY-UNITED FRACTURE.**—MR. ARBUTHNOT LANE operated on a woman, æt. 45, who had suffered from badly-united fracture of the neck of the left femur, which she had sustained nine months ago. She had been confined to bed since the injury, and had been unable to bear the slightest weight on the damaged limb. He made a long vertical incision over the trochanter and exposed the trochanter and the front of the hip-joint; he carefully defined the anterior ligament; this he divided vertically, reflecting its segments inwards and outwards, exposing the head of the bone in the acetabular cavity and the upper end of the neck, which was displaced upwards, backwards and outwards. He rendered the outer surface of the head and the stump of the neck raw by means of a chisel and in a similar way he cut off the extremity of the displaced neck; then by the exercise of considerable traction on the leg in a position of marked adduction, assisted by the use of powerful forceps and levers, he was able to bring the stump of the neck into apposition with the head and the portion of the neck continuous with it. He retained these fragments immovable in their position by means of two long screws, which he drove upwards

and inwards through the base of the great trochanter, the neck of the femur, and head. The divided ends of the ilio-femoral ligament were sutured carefully together. The patient was then placed in a splint. Mr. Lane said that it was unfortunate that surgeons did not treat these cases more effectually at the time of injury, since the primary treatment of these conditions by operation is comparatively easy, while the later treatment is usually exceedingly difficult, and may require, in order to carry it out, perhaps more skill than is possessed by every surgeon. It is unfortunate, he thought, that surgeons still adhere to the ridiculous fashion of fixing the foot vertically by the employment of the vertical foot-piece; by the use of such a foot-piece a proper union of the fragments of such a fracture as the one just seen is rendered impossible. He called attention to this many years ago in a paper entitled "Fallacy of the Vertical Foot-Piece" (*British Medical Journal*, 1894). He pointed out that the screws were what are called Wood's screws amongst carpenters, and are those in common use; the gauge employed was about nine inches. Except in this variety of fracture he only employed short screws, together with a rigid or flexible steel plate, the character of the latter varying with the form of the bone and the functions required of the plate. He used screws in three gauges; these are threaded up to the head. The gauges are 3, 5, and 7. Those in the 3 gauge are for the bones of infants, and are of three-eighths and half an inch in length; those in the 5 and 7 gauge are one-half and five-eighths of an inch in length. This length is sufficient to traverse the thick compact tissue, and they are sufficiently strong to secure a plate firmly even when exposed to great strain. By using only the proximal compact tissue the surgeon is relieved of the trouble of perforating both layers of the compact tissue and of the difficulty of finding the hole which he had made in the distal compact tissue when driving in the screw. No security is lost by the use of the specially threaded screw, since in the ordinary screw only the distal compact tissue engages and secures the thread, the proximal compact tissue exerting no retaining influence on the smooth barrel. By the use of screws in three gauges it is only necessary to have three drills, so reducing the number of these instruments required. The splint he finds most useful for the treatment of fractures of the femur is one devised by his house surgeon, Mr. Chapple, and made by Messrs. Down Brothers. It presents very many advantages over the double Thomas's splint, which was the one he had employed previously—facility of application, comfort in its use from the point of view of the patient, and capacity to flex the knee-joints at any time, so obviating the stiffness of the knee which so frequently complicates fractures of the femur.

The patient made an uninterrupted recovery

### OPERATION FOR PROGRESSIVE CHRONIC TUBERCULOSIS.

—The same surgeon operated on a man, æt. 24, who was suffering from a discharging psoas abscess with tuberculous lesions elsewhere. The patient had been in the hospital some time, and in spite of treatment by absolute rest, tuberculin, etc., it became apparent that the case could only end unsatisfactorily, and at no distant date. Mr. Lane pointed out that this patient illustrated in a very typical manner the views that he held, namely, that the very large proportion of these tuberculous patients suffered from intestinal stasis, and consequent auto-intoxication. This is especially true in cases of tuberculous disease of the joints and glands. He considered that the auto-intoxication reduces the resisting power of the individual to the entry of the tubercle which is present everywhere. Arguing on these lines, he was of opinion that the diverting of the faecal stream from the large bowel into the rectum might so improve the patient's resisting power to tubercle by relieving him of his intestinal auto-intoxication as to enable him to meet and overcome his disease. This particular patient presented the symptoms of intestinal auto-intoxication in a most characteristic manner. He had explained to the patient the views he held on the subject, and the latter very willingly accepted the treatment suggested.

(a) "Excretory Irritations." By D. Walsh, M.D. London: Baillière Tindall and Cox. 1897.

He opened the abdomen and exposed the large intestine, which showed in a very marked degree the mechanical conditions which Mr. Lane has so frequently described as characteristic of intestinal stasis. He divided the ileum about four inches from its termination, including each of its proximal and distal extremities, by means of an encircling catgut ligature and embedding the resulting stumps securely by means of purse-string sutures; he then united the proximal end of the ileum to the lower limit of the sigmoid by lateral anastomosis. The interval between the meso-sigmoid and the mesentery was obliterated by an encircling suture which perforated the peritoneum at intervals. An œsophageal tube was then passed through the anus, rectum, the aperture of anastomosis and the ileum for a distance of a foot, the open aperture of the tube being sutured to the margin of the anus. This use of the tube is of greatest service, Mr. Lane said, in these cases, since it carries away at once the gaseous or fluid contents of the small intestine which may otherwise hesitate to pass through the newly-formed anastomosis, and in this way renders the patient much more comfortable than he would otherwise be. The tube is kept in position for five or six days, when it is removed. The operation was rendered somewhat difficult by the presence of a large iliac abscess on the left side, which had undermined the skin for some distance around.

The patient made an uninterrupted recovery, and expressed himself as being delighted with the result of the operation. His appetite and general condition are much improved. Too short an interval has elapsed, Mr. Lane remarked, to enable one to speak dogmatically of the ultimate result in this particular case. In a somewhat similar case of a child, in which the same operation was performed in the Hospital for Sick Children, the improvement that has followed upon operation is most marked. Should this operation prove successful in a class of case in which ordinary treatment would appear to offer little or no result, a very large field would be opened up to the surgeon. It is very possible that other diseases, such as true rheumatoid arthritis, which would appear to arise in the presence of a severe degree of intestinal stasis, may be efficiently dealt with in the same manner. It is only by proving or disproving these views by putting them to the test of operation that we can arrive at any definite conclusions.

## TRANSACTIONS OF SOCIETIES.

### THE ROYAL SOCIETY OF MEDICINE.

#### CLINICAL SECTION.

MEETING HELD FRIDAY, DECEMBER 10TH, 1909.

The President, A. PEARCE GOULD, Esq., M.S., F.R.C.S., in the Chair.

MR. JOHN R. LUNN showed a  
CASE OF ACROMEGALY.

The patient was a woman, æt. 52, and was a typical example of the disease in an early stage. The tongue and lower lip were enlarged, and the lower jaw protruded. The nasal cartilages were thickened. The skin and hair were coarse, and the hands short, broad and square-looking. Intelligence was normal.

Dr. ROBERT MILNE showed a case of  
ACROMEGALIC GIGANTISM.

The patient, a boy, æt. 19, was at the age of 9 a little under average height, but otherwise quite normal. At 13 he began to grow very rapidly, and suffered from pains in the legs and back and general weakness. At 15 he was 6ft. high, and at 16, 6ft. 4in. In November, 1909, he was 6ft. 11in. His hands had increased out of proportion to the rest of the body, and measured 9½ inches long. His mental powers were above the average, and he was cheerful and sociable. A skiagram showed an enlargement of the pituitary body. Others of his family were of uncommon height.

Dr. ROBERT MILNE also showed

#### TWO CASES OF ACHONDROPLASIA.

Both were typical examples of the disease. He considered that the condition arose in arrested development of the long bones from the 3rd to 6th month of fetal life, the proximal segments being relatively more affected than the distal. The middle of the body was 2½in. above the umbilicus zone, and 3in. above it in the other.

Dr. McMULLEN showed a

#### CASE OF ADIPOSIS DOLOROSA.

The patient was a woman, æt. 62. The condition had started as a localised and circumscribed lipoma of one arm, five years ago, and had spread rapidly. The changes were preceded by and associated with pain along the nerve trunks, and areas of hyperæsthesia of the skin. The upper arms, back, left buttock, and sternal region were affected. Thyroid extract had been administered with moderate improvement.

Dr. GOSSAGE referred to a similar case, which had not benefited at all by thyroid. Sometimes mental deficiency was present in such cases.

Mr. WARREN LOWE said that he had noted that in cases of symmetrical lipomata an area of hyperæsthesia, or perhaps actual pain foreshadowed their formation.

Dr. LEONARD WILLIAMS believed that the condition was due to errors of internal secretion, and mentioned a slow pulse, dry skin, and subnormal temperature as evidence of constitutional disturbance. It was allied to myxœdema, and only occurred in women at the menopause, and was probably due to a want of coincident decline in the activity of the ovaries and thyroid. Possibly other internal secretions were also defective.

Dr. POYNTON said that in his experience patients who required thyroid took it readily, whilst those in whom it was not beneficial were easily overdosed.

Sir DYCE DUCKWORTH thought that, under the name of Dercum's disease, several different conditions associated with the formation of fatty tumours had been described. The course of the disease was often modified by thyroid treatment.

Dr. GALLOWAY thought that several cases described under this title had been improperly so named. In one type serious vasomotor disturbance and destruction of skin occurred. He had made a post-mortem examination in such a case, and found marked degeneration of the muscles all over the body.

Dr. PARKES WEBER said that the peculiarity in these cases was the absence of diffuse lipomata. Such occurred nearly always in women, whilst diffuse lipomata were nearly always found in men.

Dr. McMULLEN, in reply, said that the pulse-rate had never been below 80. The mental condition was active. The menopause had occurred 18 years ago, but the lipomata only appeared five years ago.

Dr. HERRINGHAM showed a

#### CASE OF RHEUMATOID ARTHRITIS WITH ALBUMINURIA, AND WITH GREAT ENLARGEMENT OF THE LIVER.

The boy, æt. 15, was a typical and severe case of the disease. In 1907 the axillary glands were enlarged, and also the spleen, slightly, but at that time there was neither albuminuria nor an enlarged liver. The liver now reached to the iliac crest, and was smooth, hard and painless. The urine contained a large quantity of albumin. No amyloid reaction had been obtained in urinary casts, which were hyaline, granular, and epithelial.

Dr. POYNTON said that Dr. Beattie had found definite lardaceous degeneration of the liver in protracted cases of rheumatism and anæmia. In Dr. Still's cases the liver sometimes showed slight fatty enlargement.

Dr. PARKES WEBER said that liver enlargement in children was almost always due to fatty change.

Sir DYCE DUCKWORTH said that from the physical examination, he thought that the condition was that of amyloid disease, and suggested the administration of large doses of iodide of potassium.

Dr. H. D. ROLLESTON thought that the absence of lardaceous reaction in the casts was not sufficient to

eliminate the diagnosis of lardaceous disease. Renal disease in rheumatoid arthritis was well known.

Dr. HERRINGHAM, in reply, said that the renal disease which occurred in rheumatoid arthritis was a true nephritis, and not a degeneration.

Mr. ALBERT CARLESS showed a patient who had been operated upon for

IMPACTION OF A LARGE CALCULUS IN THE LOWER END OF THE RIGHT URETER.

The patient was a man, *æt.* 29, who had been admitted to hospital for supposed stone in the kidney. Radiographic examination showed a large shadow, dense and ovoid, on the right side of the pelvis and just below the brim. A median laparotomy was performed for exploratory purposes, and the stone removed later from a lateral incision, after the peritoneum had been turned forward. The ureter was dilated to the size of a dilated small intestine, and filled with pus. The stone weighed 803 grains, and was composed of uric acid. The patient had recovered, with a ventral hernia.

Mr. THOMSON WALKER said that 816 grains was the heaviest weight for a ureteral calculus that he could find in the literature. In such large stones the kidney was usually destroyed. The operation usually performed was extra-peritoneal, and the mortality was very low.

Mr. DREW recalled three cases in which he had removed stones from the ureter, and in all three ureteral strictures arose.

The PRESIDENT said he had removed a large stone from the ureter, but one which was smooth, like that exhibited, and no stenosis had occurred.

Mr. W. G. SPENCER showed a patient, illustrating TREPHINING FOR GENERAL EPILEPSY.

The fits had started when the boy was *æt.* 14. A shallow depression had existed on each parietal bone, midway between the bregma and the parietal eminence. The fits, which were without localising significance, persisted until 1906, when he was 20 years old, and backward and uneducated. The patient was then trephined, the depression bone being removed. Only one slight fit had occurred during the three years since the operation, and he was making progress with a tutor.

Dr. F. J. POYNTON showed TWO CASES OF CONGENITAL ŒDEMA, WITH CARDIAC DEFECT IN MOTHER AND DAUGHTER.

The mother, at  $\frac{1}{2}$  years of age, had been noted as having congenital Œdema and a cardiac bruit. The Œdema had slowly increased. The heart showed an enlarged area with forcible impulse, and a mitral systolic murmur with accentuated pulmonary second sound could be heard. The daughter was *æt.* 7, and the youngest of seven children, and the only one with this condition. The murmur was also systolic in time, and heard at both base and apex.

Mr. J. W. THOMSON WALKER showed a man, *æt.* 55, on whom resection of the bladder for malignant disease had been performed. By cystoscopy a large growth had been seen projecting into the bladder, extending from the outer tip of the left ureter upwards on the left lateral wall almost to the apex. No sign of infiltration was seen beyond the mass, nor of secondary intra-vesical growths. Recovery after resection had been uneventful.

Mr. CHARTERS SYMONDS showed a man, *æt.* 65, the subject of excavating rodent ulcer of the face, under treatment by radium. The condition had been present for over 27 years, and many operations had been done. X-rays had not proved successful. The treatment was having good effects, and it was hoped that the case would be shown again later.

Mr. ARCHIBALD SMITH and Mr. JAMES McDONAGH showed a case of pachydermatocoele. The swelling was tripartite and situated in the scalp midway between the left ear and occipital protuberance. The occipital nerve, enlarged and tender, could be felt between the middle and posterior parts of the swelling. Sections prepared from a fragment removed under local anaesthesia, were exhibited.

Mr. FREDERICK EVE showed a case of arterio-venous aneurysm with exophthalmos, following an injury to the head. J. N., a man, *æt.* 30, had fallen on the

back of his head from the foot-board of a rapidly moving motor-bus. Next day he had headache and double vision, and later the left eyeball began to swell and cause pain. When seen three weeks after, there were proptosis, ophthalmoplegia externa, and ptosis of the left side. The pupil reacted and vision was good. Pulsation of the eyeball could be felt, and a loud systolic bruit could be heard over the globe, the supra-orbital region and temple. These ceased on compressing the left carotid artery. When exhibited, the proptosis was the same, but the pulsation had diminished. The disc had become swollen.

Mr. FREDERICK EVE also showed a case of partial luxation of the odontoid process. It was that of a girl, *æt.* 17. The condition followed an injury in March, 1908. In October, 1908, extension was applied for a month, and she was discharged improved, with a jacket and head support. Flexion of the neck was good, extension fair, but rotation very limited. Radiogram showed considerable backward displacement of the odontoid process.

Mr. FREDERICK EVE also showed a case of transverse fracture of both patellæ, with much separation of the fragments, treated by operation. It was that of a man, *æt.* 41. The fragments had been wired after dissecting out the fibrous bond of union, and freely dividing the insertions of the two quadriceps. Now, four years later, he could do his work as a lighterman.

Mr. H. T. PATERSON showed a gumma of the breast simulating malignant disease. The breast had been removed from a female, *æt.* 36, because it was thought to be the seat of sarcoma, and such was the report of the pathologist on a piece removed at the time of the operation. Further investigation demonstrated its inflammatory nature.

Mr. JOHN D. MALCOLM showed a woman, *æt.* 68, for whom he had performed cholecyst-duodenostomy for acute emaciation. A biliary fistula had been left after operation for jaundice, and this was followed by rapid emaciation. As a last resort, the abdomen was re-opened and communication made between the fundus of the gall-bladder and the duodenum. The patient's nutrition then steadily improved.

Mr. ALBERT CARLESS said he could recall a similar case, and also another in which, on the other hand, although all the bile flowed externally, no emaciation resulted. There was some other factor besides merely loss of bile, which determined the wasting.

Mr. PARKES WEBER showed a case of a woman, illustrating a successful result following Talma's operation for hepatic cirrhosis, and also a case of Van Recklinghausen's disease in a woman, *æt.* 45.

Mr. BALLANCE showed a man, *æt.* 29, illustrating recovery after trephining for fracture of the basis cranii.

Mr. Sargent also showed a case.

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

### SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, NOVEMBER 12TH, 1909.

The President, A. H. BENSON, F.R.C.S.I., in the Chair.

### PRESIDENT'S ADDRESS.

THE PRESIDENT delivered an address "Concerning Trachoma," which we hope to print in our next issue.

Dr. DRURY read notes of a case of HYPERTROPHIC CIRRHOSIS WITH ALCOHOLIC PARALYSIS, which appeared in our issue for December 1st.

### PERFORATED GASTRIC ULCER.

Dr. J. B. COLEMAN, C.M.G., exhibited viscera of a woman, *æt.* 34, who died from symptoms of gangrene of the lungs, consecutive to perforated gastric ulcer. The autopsy revealed a small ulcer, which had perforated, on the posterior wall of the stomach, two inches from the fundus. A sinuous track from the perforated ulcer led, by a perforation in the diaphragm, into an abscess cavity, one and a

half inches in diameter, between the diaphragm and the base of the left lung. The lower lobe of the left lung contained several abscesses and gangrenous areas.

#### STERCORAL ULCERS IN SMALL INTESTINE.

Dr. ROBERT ROWLETTE showed a specimen of above. The organ had been obtained, post-mortem, from a woman who had suffered from diarrhoea for seven years. For the last two years she had not passed a solid motion. The lower three feet of the ileum was crowded with small ulcers, which had destroyed the greater part of the mucous membrane of the region. The ulcers were clean cut, reaching to the muscular layer, and some of them contained sloughs. In the cæcum was similar ulceration of less extent. In the ascending colon, close to the ileo-cæcal valve, was a stricture, whose lumen did not admit a lead pencil. The stricture was found to be due to scirrhus carcinoma. The condition of ulceration Dr. Rowlette believed to be identical with that occurring in the large intestine as the result of stasis of the contents. Of the four theories put forward to explain the ulceration—(1) irritation by scybala, (2) obstruction of the vascular supply by stretching, (3) bacterial invasion, (4) toxic solution, he inclined to accept the last.

#### OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD IN THE ROOMS OF THE MEDICAL SOCIETY OF LONDON, DECEMBER 9TH, 1909.

Mr. W. H. JESSOP, F.R.C.S., Vice-President, in the Chair.

Mr. S. STEPHENSON showed a case of tubercle of the choroid, shown originally on October 17th, 1907.

Mr. Bishop Harman showed three cases: (1) Abnormal congenital pigmentation of one eye. (2) Retinitis nœvus. (3) The diaphragm test. Finished models of the instrument and its accessories.

Dr. Rayner D. Batten showed an orbital frame for eyeglasses, and its adaptation for a ptosis prop.

Mr. A. H. Payan Dawney, opacities of cornea of unusual character.

Mr. Hepburn exhibited a case of hæmorrhages of the macula.

#### DEATH OF THE LATE PRESIDENT, MR. MARCUS GUNN.

Before the papers of the evening were read, the Chairman alluded in very sympathetic terms to the recent demise of last year's President, Mr. R. Marcus Gunn. He alluded to the large number of contributions which the late distinguished member had contributed, all marked by great accuracy and care in observation. Mr. Jessop also dwelt affectionately on Mr. Gunn's personal qualities, and his faculty of endearing himself to all with whom he was brought in contact. It was resolved to send a letter of condolence to Mrs. Gunn and family.

Mr. DOYNE read a paper, describing a form of CONJUNCTIVITIS

in which the Meibomian glands were affected with staphylococcus aureus. This, he described, as giving rise to definite acute attacks, especially after exposure of the eyes. He also pointed out that many cases described as chronic conjunctivitis were due to this cause, as well as many other cases of marginal blepharitis.

Mr. Doyne showed a member of a fresh family suffering from guttate choroiditis, which he described some years ago, and gave a brief description of the condition. He also read a brief note on a condition that he described as myopic degeneration of the lens, and had pointed out the condition to the Society in 1886, when he showed a patient suffering from this form of nuclear degeneration.

He also read notes of a form of iritis which he described as guttate iritis, occurring in elderly and gouty persons. It presented the appearance of one or more warts at the pupillary margin of the iris, which came on without any noticeable inflammatory appearances and sometimes disappeared without giving rise to any inflammation. At other times inflammatory

symptoms appeared and adhesions to the lens took place.

Mr. HARMAN, in discussing the first paper, said that seven years ago he made bacterial cultures from the normal healthy eyes of school children, by passing a platinum loop along the mouths of the Meibomian glands, and in every case he got enormous numbers of staphylococcus aureus and albus.

Mr. DOYNE, in reply, asked members to look out for such cases and endeavour to ascertain the exciting cause, but for five days nothing but water should be used in the eyes.

Mr. Doyne's other papers were discussed by Mr. Nettleship, Mr. Harrison Butler, and Mr. J. E. Adams.

Mr. M. S. MAYOU read a communication entitled

#### A CONGENITAL SARCOMA OF THE ORBIT.

He pointed out that the interest in this case lay partly in its extreme rarity and partly because of its clinical resemblance to the proliferating cysts.

CASE.—A. P., male, æt. 12 days, was admitted to the Central London Ophthalmic Hospital on March 13th, 1908. No eye had been seen since birth on the left side. The patient was a strong, healthy infant, and presented no other congenital abnormalities. The right eye was to all appearance normal. Filling the left orbit and protruding from between the lids, which could not be closed, was a red, slightly oedematous mass. It was irregular on the surface, and covered by the epithelium of the conjunctiva, except where it was exposed in the palpebral aperture, where it had started to ulcerate. There was no enlargement of the preauricular gland, and no eye could be seen. On March 13th the orbital contents were eviscerated, leaving the eyelids in position. The child made a good recovery, the wound granulating and healing over with epithelium.

On June 16th, 1908, the child returned to the hospital with a large recurrent mass, filling the entire orbit and bulging forward the upper lid and protruding between them. Complete evisceration of the orbit was performed, the child making a good recovery. After the operation the patient attended the hospital for four weeks, but since then has been lost sight of.

The contents of the orbit submitted for examination were hardened in formol. The eye, which was embedded in the upper part of the tumour, had been cut open and the sclerotic divided posteriorly in several places. It appeared about the normal size, the cornea, anterior chamber, iris, ciliary body and lens being normal. The condition of the posterior part of the globe could not be drawn out, but there was no evidence of any cystic protrusion therefrom. No definite orbital structure could be recognised, the whole being involved in the tumour. It was composed of medium-sized spindle cells. The walls of the vessels within the tumour were composed for the most part of its cells. Hæmorrhages had taken place into the growth in many situations. The recurrent tumour, examined microscopically, exhibited the same characteristics as the primary tumour, except that the hæmorrhages were not so numerous.

The typical microscopical appearances, together with the recurrence of the disease, led him to believe it to be a spindle-celled sarcoma of the orbit, developing during intra-uterine life. He had been able to discover the records of two similar cases which exhibited much the same characteristics.

Messrs. A. P. L. WELLS and M. S. MAYOU read a paper on

#### LYMPHOSARCOMA OF THE LACRYMAL GLAND.

They pointed out the want of proper classification of tumours of the lacrimal gland. They divided them into those derived from the epithelial, the connective, and the lymphoid tissues. The case which they brought before the Society was one of the latter type.

CASE.—M. A., female, æt. 66, was admitted to the Central London Ophthalmic Hospital on January 14th, 1909. She was a strong, healthy woman, no anæmia, no glandular enlargement. There was nothing in her previous history of note. She complained of a swelling which she had noticed for a considerable time at the upper and outer part of the left orbit in the situation of the orbital portion of the lacrimal gland.

The surface of the swelling was somewhat irregular, and about the size of a large walnut. It was soft, almost fluctuating, rounded in outline, and moderately freely movable.

From January to April whilst under observation it gradually increased in size, and on admission into the hospital on April 8th there was, in addition to the above symptoms, displacement of the eye downwards, and the tumour seemed to have become slightly attached to the margin of the orbit, which seemed thickened. There was no enlargement of the salivary or lymphatic glands, and no signs of dissemination.

On April 9th an incision was made over the tumour, which was found to be encapsuled, except in one situation, where it was ruptured. After removal it was seen to be about the size of a walnut, and surrounded by a capsule, which was evidently formed from the original capsule of the gland. This was composed of fibrous tissue, and was much thicker in some positions than in others. In some situations it was much infiltrated by the cells of the growth, whilst in one the tumour had penetrated it. The tumour consisted of round cells about the size and shape of an ordinary lymphocyte, and showed no signs of degeneration, although at some places the cells were more darkly stained and packed closer together than others. Mitosis was not marked in the cells. The vessels in the tumour were of two kinds. Some, which were evidently new, were composed of a single layer of endothelium, or, in some situations, of the cells of the tumour itself; the others, which were generally situated in the remains of the trabeculae of the gland, and were probably the original vessels supplying it, had normal coats, which were somewhat thickened.

In the literature they had been able to find eight similar cases which exhibited much the same characteristics. The points about the tumours were the late age at which they occurred—all the patients being over 38; their slowness of growth—3 to 4 years, and the absence of glandular enlargement. They also pointed out that these tumours should be differentiated from other orbital sarcoma invading the gland, and from lymphoid growths such as are found in chloroma and lymphadenoma.

Mr. ORMOND discussed the case.

#### EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD WEDNESDAY, DECEMBER 1ST, 1909.

The President, Dr. BYROM BRAMWELL, in the Chair.

Dr. EDWIN BRAMWELL showed specimens illustrative of tumour of the brain.

Dr. G. A. Gilson showed microscopic slides showing ganglion cells and nerve fibres in the auriculo-ventricular bundle.

Dr. Byrom Bramwell showed a case of pre-ataxic tabes, with gastric and intestinal crises, in which the operation for appendicitis was performed.

Mr. A. A. Scot Skirving showed patients, illustrating certain defects of memory after operation for middle meningeal hæmorrhage.

Dr. F. D. Boyd showed a case of chronic Bright's disease, illustrating the benefit of a salt free diet in the relief of œdema.

Mr. Alexis Thomson showed a boy, æt. 11, in whom on account of a periosteal sarcoma of the right humerus, the middle third of the shaft was resected and a portion of the fibula inserted in its place. This more conservative operation had been preferred to amputation at the shoulder, or interoscapula thoracic disarticulation on account of the bad results, as regards recurrence, which followed these drastic measures, it was hoped by X-raying to delay, and possibly avert, the recurrence of the growth which would probably take place.

Dr. JAMES RITCHIE, Superintendent of the College of Physicians laboratory, gave a demonstration of THE WASSERMAN REACTION.

He showed tubes illustrating complement duration,

which was the factor underlying the Wasserman test. Normal rabbit serum did not lyse ox corpuscles, but the serum of a rabbit immunised against ox corpuscles did so. This lytic power of immune serum depended on two substances, one thermostable—the complement; one thermolabile, the immune body. Heated immune serum therefore lost the power of lysing corpuscles, but gained it when complement was added. When certain substances were mixed—e.g., syphilitic serum and syphilitic antigens, or syphilitic serum and extract of normal serum, or albumen and the inactivated serum of an animal which had been immunised against the albumen—the mixture had a great affinity for complement, and fixed it, or entangled it in some way. This fixing or duration of the complement was tested for by adding the mixture of antigens, suspected virus, and complement to inactivated hæmolytic serum and ox corpuscles. If the complement had been fixed, no hæmolysis occurred, if it had not been fixed, hæmolyses did occur. The importance of measuring the doses of the various substances used, and of employing the necessary controls, was explained; the test was regarded as a very reliable one, though its exact nature was not yet settled.

Dr. DAWSON TURNER read a paper on—

#### 'THE EFFECTS AND USE OF RADIUM.'

He had had at his disposal for the last few years 45 milligrams of radium. The specimens were contained in sealed glass tubes, and in an aluminium box with a lid only 1.5th millimetre thick, therefore practically transparent to the radiations. He had not made use of the *boîtes radifères* employed in Paris; the amount of radium on them was spread out in so thin a layer that he doubted their efficacy except for the most superficial conditions. Radium rays had two chief actions:—(1) A specific effect on rodent ulcers, cancer, angioma, keloid, cicatrices, and fibrous contractions. (2) An action producing inflammation and destruction similar to that of caustics and heat. The undue action of radium on a rodent ulcer is shown by filling up of its surface, drawing in of the edges, and finally the growth over it of transparent skin. If radium is applied to healthy skin a tender red spot develops in the course of a day or two, and over this an impetigo-like crust may form. He had not observed any tendency to form the obstinate and painful  $\gamma$ -rays sore. The dose of radium is measured by the product of the strength of the preparation and the length of the exposure, what would be termed electrically the "ampere hours," but these quantities would be modified by screens, the effect of which is to cut off the less penetrating rays and to protect the superficial tissue, for only those rays which are absorbed by the skin can be affected. All the radiation can be cut off by a sufficient screen except the  $\gamma$ -rays, and these are few in number. If a superficial condition is to be attached, use no screen, and give a short exposure; the  $\gamma$ -rays predominate, they are powerful but feebly penetrative. If a subcutaneous condition is to be treated, use an aluminium screen  $\frac{1}{4}$ – $\frac{1}{2}$  mm. thick, or a lead one 1.10th mm. thick, and give a longer exposure, only the  $\beta$  and  $\gamma$ -rays will now be available. If the disease be still deeper, use a lead screen  $\frac{1}{4}$  to 1 mm. thick and give a prolonged exposure, only the hard  $\beta$  and  $\gamma$ -rays will penetrate, and they are relatively few. No after treatment in the way of dressings are necessary. Atrophies are signs of an over-dose. Dr. Turner illustrated his remarks on the properties of radium by showing experimentally the ionisation of the air which the radiations cause, and the consequent discharge of a gold leaf electroscope. He had found it of use in rodent ulcer, angioma, keloid, cicatrices, warts, simple ulcers, malignant growths, and pruritus. He referred in some detail to a series of cases treated. (1) A male, æt. 46, with a rodent ulcer, which yielded to six hours exposure to 5 mg. radium bromide of an activity of 300,000. (2) A rodent ulcer in a male of 50, cured by an exposure of five hours to 10 mg. pure radium bromide, screened only by a thin piece of parchment paper. (3) A large rodent ulcer, measuring  $2\frac{1}{2}$  by  $1\frac{1}{4}$  ins., almost healed by an

exposure of 180 milligram-hours. (4) A port-wine stain on the face of a young woman much improved by an exposure of 510 milligram-hours. (5) A capillary naevus on a baby practically cured by 3.3 milligram-hours. (6) A tumour of the palate, of doubtfully malignant nature, much improved. Other cases were also mentioned, especially of warts, on which radium acts like a charm, and leukoplakia, in which it was decidedly beneficial.

Dr. DINGWALL FORDYCE read a paper on the DIFFERENTIAL DIAGNOSIS AND TREATMENT OF A COMMON FORM OF DYSPEPSIA AND OF EARLY TUBERCULOUS INFECTION IN CHILDREN.

He first alluded to the great difficulty of deciding whether or not in a certain group of cases a tuberculous infection was present. The characteristics of the group of cases were the indefiniteness of the history, the presence of gastro-intestinal symptoms, and the absence of signs. The diagnosis lay between the two following conditions:—A form of chronic dyspepsia associated with pallor, wasting, constipation, and occasionally vomiting. The gastro-digestion is good, but fat is well tolerated. A dose of calomel gives relief, and there is no obvious organic lesion. On the other hand are cases of early tuberculous infection. The symptoms are the same; there may be a history of exposure to infection, and there are no definite physical signs. In these cases the infection is probably glandular, bronchial or abdominal. Probably the chronic indigestion of the first type not infrequently merges itself in tuberculosis. The points on which a diagnosis rest are:—(1) The capacity of digesting fat. (2) The reaction to the tubercular tests. (3) The condition of the urine. (4) The opsonic index. The urinary test referred to was the estimation of the conjugate sulphates, and neither it, nor the opsonic index were further discussed by the speaker on account of their tedious and complicated nature. The criteria on which he relied were the power of digesting fat, and the anti-reaction. He had found that while the tuberculous patient took, and took well, large quantities of fat, in the shape of milk, eggs, butter, and cod-liver oil, in the non-tuberculous cases attempts to give fat simply made the indigestion worse. A positive Pirquet reaction he regarded as definite proof of the tuberculous nature of the case.

In all cases of chronic indigestion the diet should be cut down; rest in bed, calomel, and later strychnine were of value. A good drink of water at bed-time, and baths were also advisable. Thyroid was sometimes useful, and in other cases butter-milk. In tuberculous cases, on the other hand the diet should contain plenty of protein and fat, and tuberculin should be given. Tuberculin was safe in small doses when the temperature is normal; unsafe in large doses and pyrexial cases. Sometimes the treatment has no definite effect. T.R. is preferable to P.T.R., and hypodermic injection much superior to oral administration. The dose varied from 1-10,000th mg. to an infant of nine months to 1-3,000th mg. to a child of 12 years. Injections should be repeated weekly, and the doses increased at long intervals and by very minute amounts. Any diminished vitality after an injection was considered an indication for discontinuance or diminution of the dose of tuberculin.

Dr. Fordyce's paper was discussed by Drs. Fowler, Simpson, Watson, and Boyd.

#### GLASGOW MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FRIDAY, DECEMBER 10TH, 1909.

The President, PROFESSOR MUIR, in the Chair.

#### EXHIBITION OF CASES AND SPECIMENS.

PROFESSOR MUIR and his assistants showed card specimens, in which were illustrated supra-renal tumours, and the more recent lesions discovered in relation to disease of the marrow of bone.

Dr. Stockman showed photographs which were illustrative of rheumatic arthritis and gout.

Dr. T. K. Dalziel showed an ovarian tumour, from which he had removed 6½ gallons of fluid; and Dr. J. H. Nicoll showed a number of urinary calculi, which had been removed within the past three years.

Dr. G. H. Edington showed the following specimens: Congenital prolapsus uteri, large carcinomatous ovarian tumour, cystic ovary which was removed from a hernial sac, and cancer of cæcum; along with these were illustrated stereo-photographs of various surgical conditions, and in conjunction with Drs. Finlay and Dunn rupture of various vascular structures.

Drs. Carslaw and Dr. Dunn showed specimens and microscopic sections from sporadic cases of ulcerative colitis, along with similar specimens from the Pathological Museum.

Dr. J. S. McKendrick showed polygraph tracings taken in the course of certain affections of the heart.

Dr. S. J. Cameron showed a specimen of twin ectopic pregnancy and a chorion-epithelioma, in which very little hæmorrhage had occurred in the tumour.

Dr. J. Stoddart Barr showed a microscopic preparation and photographs taken from the external auditory meatus of a former resident in Burmah, of *aspergillus nigrans*. Dr. Barr also showed cases illustrating congenital syphilitic disease of the labyrinth, of auditory vertigo, and some of the pathological appearances which were seen in the tympanic membrane and tympanum during the course of, and following, chronic otorrhœa.

Dr. Walker Downie showed some recent cases of radical operation for the cure of empyema of the antrum of Highmore, etc., case of stenosis of the larynx, and a boy recently operated on for the removal of a large thyro-hyoid cyst.

In the Electrical Department, Dr. Tomkinson showed an interesting series of cases which were illustrative of ichthyosis simplex; pityriasis vulva-pilaris; extensive rodent ulcer; tubercular, ulcerative, syphilitic and syphilitic elephantiasis, which were treated by intramuscular injection; cases of lupus; two other cases, namely, extensive favus and tinea tonsurans, which were treated by Sabouraud's method.

In the out-patient operating theatre a series of interesting cases were displayed, the more important of which were excision of elbow-joint, with X-ray photographs showing reproduction of the bones removed; cancer of colon and pylorus, by Dr. J. C. Renton.

Case of splenomegaly with the blood changes, and also a case of acromegaly, shown by Dr. Wm. MacLennan.

Dr. Barclay Ness showed a case of Still's disease in a girl, five years of age, with chronic polyarthritis and enlargement of the lymphatic glands.

Dr. Alex. MacLennan showed four cases which were operated on for cubitus varus, and made special reference to the prevention and treatment of the deformity; in addition, Dr. MacLennan demonstrated a case where a toe-nail was transplanted to the thumb.

Dr. A. B. Sloan showed a case where there was a marked retraction of the heart to the left side, due to fibroid change in the left lung.

Dr. J. H. Nicoll showed a case of congenital hypertrophic stenosis of the pylorus, with specimens and sections in illustration; also several cases of the condition treated by operation.

## CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS  
ABROAD.

### FRANCE.

Paris, Dec. 12th, 1909.

#### HOT WATER IN GYNÆCOLOGY.

By hot later in gynæcology is meant, water at 120° or 130° F. At this temperature water exercises energetic vaso-constriction of the blood vessels of the uterus; hence its employment as an hæmostatic. Besides, hot water possesses powerful resolutive properties which make it a first-class therapeutic agent in inflammatory affections. It stimulates the local

circulation, favours cellular exchanges, removes the wastes from the organs, and favours the phenomena of diapedesis and phagocytosis.

In gynaecology, its employment is indicated each time the uterus or its appendages are the seat of chronic or subacute inflammation.

It is thus that Prof. Reclus, who recommends and practiced this treatment for several years, never advises a radical operation for an inflammatory affection of these parts, without having previously tried, conscientiously and perseveringly, vaginal irrigations and rectal injections. He always begins the treatment by this method, and it is only when convinced of its failure that he has recourse to an operation.

Frequently this treatment succeeds in the least hopeful cases. Hot water is consequently a marvellous agent, but on the condition that it is employed with method, precision, and perseverance.

Vaginal irrigations, provided they are abundant (four quarts at least) may be sufficient. An injector with a double current should be employed, and furnished with an obturating plate for the protection of the vulva. To one cannula is attached an india-rubber tube conducting the water from the reservoir to the vagina; a similar tube is fixed on the other to return the liquid to a basin or pail. The reservoir or douche should be placed about 18 inches above the horizontal plane on which the patient is lying, and a thermometer fixed in the douche marks the temperature, which should always be maintained at 122° F. By this simple apparatus, found in every chemist's shop, the patient can be treated in bed without difficulty or fatigue.

To these vaginal irrigations it is frequently advisable to associate rectal injections, which reach the back part of the uterus. Prof. Reclus considers even these injections much superior to vaginal irrigation. Unfortunately, they are not always well accepted by the patient.

Where they can be given, these enemas should be administered morning and evening, about a pint at a time, and at the usual temperature of 122° F. When the cannula is introduced, the stop-cock is turned on gradually so as to give time to the intestines to tolerate the liquid. After the operation the patient keeps lying motionless for half an hour, when she may allow it to evacuate. In severe cases the hot-water bag will be placed over the hypogastric region.

Rest and heat, intus and extra, renewed as frequently as possible and applied as long as possible, such is the secret of the treatment.

As there exists, says Prof. Reclus, hardly any uterovarian affection that is not complicated with congestion of the parts, hot water prescribed as above is the first treatment, and if all the patients are not cured, great relief may be obtained in nearly every case.

With hot water and rest, it may be affirmed that any intelligent and decided woman—for the treatment is more or less severe, and sometimes painful—will almost surely get well and recover her former activity.

#### INCOERCIBLE VOMITING OF PREGNANCY.

Incoercible vomiting of pregnancy may be rapidly relieved by 5-drop doses twice a day of a solution of adrenalin (1-1,000), as proved by Prof. Rebaudi; ingestion of supra-renal preparations possess a similar action.

#### ERYSIPELAS.

Chloride of lime, 1 dr.  
Vaseline, 3 oz.

Under the influence of this ointment the temperature falls in one or two days. Complications are also avoided.

#### GERMANY.

Berlin, Dec. 12th, 1909.

#### NEUTRALON.

At the Verein für Innere Medizin, Hr. Erhmann communicated a note on Neutralon (Kahlbaum). After discussing the preparation usually made use of in affections of the stomach, bismuth, silver nitrate, bicarbonate of sodium, etc., their occasional disadvantages, and the objections to their employment, he drew attention to neutralon, which, as he claimed,

possessed manifold advantages. It was a silicate of aluminium. It had all the useful properties of the before-mentioned preparations without any of their disadvantages. It formed a strong combination with hydrochloric acid, was a "covering" powder, and astringent; on the other hand, it had no action on the bowels, and never caused symptoms of intoxication.

Hr. Rosenheim said he had been using the preparation for the last two years in cases of neurogenous hypersecretion and hyperacidity, and he could strongly recommend it. In many cases it undoubtedly did more than the older well-tried remedies. The indications for it were:—(1) Irritative conditions with motor insufficiency; (2) Irritations of sensible origin; (3) Ulcers, here the prompt action of large doses of bismuth on the empty stomach was not present. Where the development of acid was high, a teaspoonful of neutralon was to be given after a meal in 100 grm. of water.

R. Neutralon, 70 gr.

Aq. ad., 4 oz.

Ft. haust.

A like draught to be taken after each meal.

Not the least disagreeable effects had been observed from taking the medicine.

#### GUAIACOL AS AN ANÆSTHETIC AND ANTIPHLOGISTIC.

In the *Therapie der Gegenwart*, 7/09, Hr. Hecht, of Beuthen, has an article on this subject. He says that in the treatment of inflammatory affections, the anæsthetics have of late acquired an importance they did not before possess, from the knowledge recently gained that a considerable amount of mischief was caused in these affections by the pain itself. The pain alone caused a disturbance of the tissues, whereby the natural processes of recovery were retarded. This being so, relief of the pain alone was a distinct aid to recovery. By relief from pain the tissues were enabled to recover their normal vascular tone. Amongst others, guaiacol acted most effectually as an anæsthetic and remedial agent in dilutions of from 10 to 20 per cent.

(1) In painful affections, such as articular rheumatism, caries of the wrist-joint, hysteria, the pain of tabes dorsalis, neuralgias, and neuritis.

(2) Herpes zoster (application of a 10 per cent. guaiacol ointment), pruritus vulvæ (10 to 20 per cent. guaiacol-vasogen ointment), pruritus nervosus, eczema papulosum, itching affections of the skin. The writer uses 10 per cent. of guaiacol dissolved in spirits of camphor.

(3) Minor surgery (He applies 1 to 5 grm. of guaiacol to the skin), further, in rhinology, otology, and laryngology, Laurens, after painting the parts with a 5 per cent. solution of guaiacol in olive oil, performed paracentesis of the tympanum, cauterisation of the lower turbinated bone and removed nasal polypi without pain.

(4) Erysipelas (Schnierer used a 50 per cent. solution of guaiacol in olive oil). The writer also made use of it in the eczema of infants, with a good result for the general condition also, whilst no ill effects were ever observed. He painted the parts affected twice a day with guaiacol, ichthyol, each 5 parts camphorated spirit 40 parts. In cerebro-spinal meningitis he painted on 0.75 to 1 grm. of an ointment consisting of 4 per cent. of guaiacol made up with equal parts of vaseline and lanoline. In furuncles of the skin and external auditory passages, he uses a 20 per cent. solution. In commencing phlegmons, lymphangitis, phlebitis, tendovaginitis, periostitis, he used a 10 per cent. guaiacol-vasogen ointment. Serous pleural exudations were absorbed after daily painting with guaiacol 5 parts, tr. iodi 25 parts. In croupous pneumonia of children the single dose rubbed in should not exceed 0.5 grm., and the day's dose not go beyond 1.5 grm. Cardiac affections were a contra-indication. Caution should be exercised with children and delicate females; in pulmonary tuberculosis a favourable effect was observed, as regarded the fever, by rubbing in a 10 per cent. guaiacol ointment, the pains in the chest and back were also relieved. He recommended Sonnen-

feld's formula: guaiacol 2 parts, tr. iodi and glycerine, each 10 parts.

The disagreeable bye-effects formerly observed (profuse sweats, rigors, collapse, vomiting) did not appear when the doses were appropriate. The writer as a rule adhered to the following formulæ:—

- R. Guaiacol, 10.0.  
Menthol, 5.0.  
Mixt. oleoso-bals., ad. 100.0.  
M. D. S. "The Ointment."  
(For neuralgias.)
- R. Guaiacol, 5.0.  
Ol. neroli, gtt. iii.  
Lanolia.  
Vaselin. flav., ana ad. 50.0.  
M. D. S. "The Ointment."  
(Tuberculous fever.)
- R. Guaiacol, 2.0.  
Tinct. iodi.  
Glycerin, ana, 9.  
M. D. S. For painting.  
(Serous pleuritis.)
- R. Guaiacol, 5.0.  
Ung. Ichthyol, 45.0.  
M. ft. ung. (For rheumatism.)

### AUSTRIA.

Vienna, Dec. 12 b, 1909.

#### BIER'S LOCAL ANÆSTHESIA.

At the Gesellschaft der Aerzte, Jerusalem exhibited a patient, a male, who had a bullet from a revolver lodged in one of the metacarpal bones of the hand, which he removed by means of Bier's "Venæ Anæsthesia." First an Esmarch binder is applied to the arm, after pressing all the blood from the finger to the upper arm. Then an anæmising binder is put on both upper and lower arm, and the limb is then ready for the injection of "Novocain," which consisted of 100 c.c. of a  $\frac{1}{4}$  per cent. of the alkaloid. This was injected into the vein of the arm, and immediately produced anæsthesia in the whole length of the limb. After similar preparation, he has removed different foreign bodies by this form of anæsthesia, with excellent results; one in particular was a needle lodged in the elbow-joint.

Eiselberg was of opinion that this local anæsthesia might be useful in some cases, but their range must be very limited, and could only apply to those that were unsuitable for general narcosis.

Hirsch showed another case from which he removed a fractured os naviculare carpi, or os scaphoid, from the back of the hand. He preferred extirpation in these fractures to the more conservative method, which always gives bad results owing to the non-formation of callus, which leads to thickening and shrinkage of the capsule.

#### EXPERIMENTAL TRANSMISSION OF TUMOURS IN RATS.

Ranzi and Ehrlich treated the Gesellschaft to another course of experiments in transferring sarcomatous tumours to rats. When any of these morbid growths were inserted below the skin, or implanted in any of the organs, the results were not always constant. The tumour after insertion gradually increased, as it had done from the beginning, in others it increased more rapidly, while in a third class it gradually shrank and disappeared. If an animal which had previously been infected with the tumour virus had a tumour implanted as above, it would not increase, or if it did, only for a short time, and then wither and die.

Albrecht said the "parabiotic" condition of the animal had had some influence over the growth of the tumours, and in his own experiments he found that it invariably inhibited the morbid growth. He found that when two parabiotic mice were vaccinated with carcinoma, the tumour when inserted would remain quiescent, but as soon as the parabiosis was exhausted, the tumour rapidly increased.

Landsteiner thought the organ or, site, in which

the tumour was implanted might have an influence on the growth of the tumour.

#### HEREDITARY DEAFNESS.

Hammerschlag gave a long account of his experiments on different kinds of mice, and his firm belief in Mendel's law of heredity. He found that he could not transmit deafness from animal to man, or *vice versa*. He enunciates the hypothesis that hereditary deafness of man is quantitative and not equivalent to the hereditary deafness of the dancing mouse, which, if followed through a few generations, with a pure breed, can produce an extraordinary pathological change. This cannot be proved in the human subject, but he admits there is always difficulty in the purity of breed in the latter.

#### MICROCOCOCCUS TETRAGENUS.

Fedesko presented a young man, æt. 19, who was received into hospital on account of septicæmia. Patient, a farmer, had been always healthy till four months ago, when a severe itching commenced all over the skin, resembling scabies, which caused him to scratch till blood flowed. Shortly after, a furuncular swelling about the size of a two-shilling-piece, with a few smaller ones around, formed on the arm. Three weeks before admission, rigors followed by fever, with pain in head, abdomen, and all the long bones. The carbuncle was opened, and a greyish, gluey fluid emitted. At this time the blood was examined, and micrococcus tetragenus found. In the course of a week after the opening, the temperature fell suddenly and the wound closed, leaving the patient very feeble, with pain and swelling in both legs about the calves, presumably due to thrombi in the veins.

The blood showed a highly polynuclear form of leucocytosis, with eosinophile of 3.5 per cent. At the present time no tetragenii are present in the blood, which seems to have come from the buccal cavity, being a common part of the flora of the mouth in farmers, as it is very common in all pustular eruptions in cattle, the dry scales of which the farmer is likely to breathe, or what is more probable, he may have been inoculated from the animal after a scratch or an abrasion of the cutaneous surface.

## FROM OUR SPECIAL CORRESPONDENTS AT HOME.

### EDINBURGH.

#### FREEDOM OF EDINBURGH FOR SIR WILLIAM TURNER.

—The freedom of Edinburgh was conferred on Principal Sir William Turner and the Rev. Alexander Whyte, D.D., in the Synod Hall, Edinburgh, on December 10th. On the advice of his medical attendant, Dr. Whyte abstained from receiving the honour in person, and it was intimated that it would be privately conferred on him at a later date. Lord Provost Brown, at the outset, said they were met for the purpose of bestowing on two of their citizens the highest honour the city could bestow. He referred in eulogistic terms to Sir William Turner's work in connection with the University during the fifty years which had passed since he left his native Lancaster and came to reside in Edinburgh. They recognised in Sir William Turner one of their oldest and most eminent citizens, who was not merely the official head of the University, but represented, as no other man could do, the life and work of the University since it was taken over from the Town Council fifty years ago. Sir William Turner, in reply, said he was deeply moved by the honour they had paid him. He felt that it was not on personal grounds but in his capacity as Principal of the University that he was privileged to appear there that afternoon. He then sketched the rise of the University of Edinburgh, which was a child of the Reformation, and not, as St. Andrew's, Aberdeen, and Glasgow were, created by a Papal Bull. In October, 1583, the College was founded under Robert Rollock, and there were possibly between 50 and 60 students enrolled, for in the following year Rollock conferred the degree of M.A. on 48 students. From that time on until 1858 the patronage of the University

was exercised by the Town Council, and the historical relation of the University to the municipality in regard both to administration and patronage, was preserved, in a qualified form, to the present day. The interest taken by the Corporation in the University rested on a wider foundation than that of administrative co-operation; the town realised that in the University they possessed a real and virile asset, which contributed in no small degree to the renown of Edinburgh. Sir William concluded by a personal reference to the courtesy of the thousands of students he had taught, to the confidence shown him by his colleagues in the Senatus, and to the pride which he felt in having gained the esteem of the Lord Provost and his predecessors in the civic chair.

**PROPOSED NEW HOSPITAL IN EDINBURGH.**—A private meeting of ladies and gentlemen interested in a proposal to establish a hospital for diseases of women was held in the City Chambers, under the chairmanship of the Lord Provost, on December 7th. The promoters of the scheme have in view those who are able and willing to pay towards the expense, but are not able to bear the whole cost of an expensive operation, and who, from independence or sensibility, do not care to go into such a hospital as the Infirmary, which is also a teaching school. Dr. Alexander James spoke in favour of such a hospital, which would foster the traits of independence, delicacy, and refinement. Treatment would never be free; payment would be at the rate of 10s. to £1 per week. Canon Stuart also supported the scheme, which would relieve both the better working and shopkeeper class. In the discussion which followed, and in some correspondence in the daily Press, there was a good deal of opposition to the proposed hospital. It seems that the promoters of the scheme intended to have the staff limited to men, and it was pointed out that an institution on analogous lines, staffed by women, already existed in Edinburgh, and the question of the possibility of excluding the latter was broached. It was also pointed out that a nursing home, managed by a medical committee, the charges in which were very moderate, had been in operation for a number of years. The understanding apparently was that the new institution was to have an honorary staff, and that no medical fees were to be charged to the patients. Considering how much hospital abuse there already is in Edinburgh, it would seem as though the need for a paying hospital should rather be met by extending the existing nursing home, where moderate fees, alike for board and for medical attendance, are charged, than by starting a hospital, strictly so-called, in which the patients pay a small contribution towards their keep, but secure the chief benefits—namely, medical advice and treatment—as gratuitously as in any other charity.

### GLASGOW.

**THE PROPOSED TESTIMONIAL TO PROFESSOR CLELAND.**—The committees, which were appointed in the autumn, for the appropriate recognition, in connection with the University, of the long and distinguished services of Professor John Cleland and Professor William Jack, have decided to close the list of subscriptions at the end of the present month. Upon the amount subscribed will depend, in a large degree, the precise form which the recognition shall take in each case, but the committees have thought that in the case of Professor Cleland it would be eminently appropriate to provide a fund for the advancement of anthropological and anatomical science, and a similar fund in the case of Professor Jack for the advancement of mathematical science; and in addition it might be possible to arrange for presentation to the University, in one or both cases, of a portrait or bust. These movements have been cordially received by a large circle of friends, and particularly by former students.

**CLINICAL TEACHING IN GLASGOW.**—The draft provisional order in regard to clinical teaching in the Royal Infirmary was before the University Court on December 9th, as also replies from the Royal Infirmary, the Muirhead trustees, and the Governors of

St. Mungo's College, as to the constitution of the Board of Curators. The provisional order was the subject of a long discussion, the representatives of the Western Infirmary holding that their rights would be prejudiced by the creation of chairs, as proposed. It was agreed to lodge the provisional order in Parliament next week, and, in response to the request of the Western Infirmary, to hold a conference between their representatives of the Court, that conference to report to the Court whether amendment of the provisional order was desirable.

### BELFAST.

**NEW COTTAGE HOSPITAL AT BANGOR, COUNTY DOWN.**—The foundation stone of a new Cottage Hospital was laid last Thursday afternoon at Bangor by Miss Connor, a generous benefactress to that town, under the presidency of the Dowager Marchioness of Dufferin and Ava. Thanks to the help of Lady Clanmorris, of Bangor Castle, a most suitable site has been obtained, at the south end of the new public park, with fine views over Bangor Castle edmesne and the golf links. All the medical and surgical wards are on the ground floor, while the nurses' rooms are on the first floor. An operating theatre, well lighted, is at the back of the hall, and behind it are the kitchen, etc.

**BALLYMENA COTTAGE HOSPITAL.**—The annual meeting of the Cottage Hospital at Ballymena, County Antrim, was held last Friday, when a very satisfactory medical report was read by Dr. D'Evelyn. The number of cases treated during the year was 103 intern and 35 extern, and the year closed with a balance in hand of £29. On the motion of Mr. C. McConnell, J.P., seconded by the Rev. Thos. Haslett, M.A., the following resolution was unanimously adopted: "That the best thanks of the meeting are due, and are hereby accorded, to the medical gentlemen who have given their kind and gratuitous services to the hospital."

**QUEEN'S UNIVERSITY: LECTURE ON GREEK MEDICINE.**—The first meeting of the Queen's University Classical Society was held last Friday evening, when a lecture was delivered by Professor Henry on "A Chapter in the History of Ancient Medicine." The lecturer in a most interesting manner traced the rise of the worship of Æsculapius in Greece, and described the manner of the worship at its two great centres, Cos and Epidorus. It seems to have been the custom for patients who had been healed at the shrine to present to the shrine models of the afflicted part, or tablets giving a full description of the disease and the manner of its healing, and it is these latter, practically "case sheets," which have now been deciphered, and which throw a vivid light on early Greek medicine. Very few of the cases are what one would call bare miracles; generally the god was supposed to work through means, which often included well-recognised therapeutic agents. Professor Lindsay, in moving a vote of thanks to Professor Henry, said that they should pause before coming to the conclusion that the Greeks had not accomplished much in medicine. The treatment of the patients awaiting cure in the temples was practically hospital treatment, with rest, quiet, careful regulation of diet, and often hydrotherapy. The priestly physicians also made much use of suggestion, and they even provided the patients with musical and dramatic entertainments. Then again, the surgical instruments which had been discovered at Pompeii, and which might now be seen in the museum at Naples, showed that the Greek surgeons who made and used them were worthy of deep respect. The motion was seconded by Mr. K. T. Frost, the newly-appointed Lecturer in Archæology, who described the treatment of a man whom he had seen accidentally injured during some excavations in Crete: his friends fell back upon pagan rites which had been in use in the island before the days of Homer.

On December 7th Lady Ancaster presided at the half-yearly meeting of the general council of the Cottage Benefit Nursing Association at Denison House, Vauxhall Bridge Road.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

## POWERS OF THE GENERAL MEDICAL COUNCIL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It was with a certain uneasy feeling many of us read some of the recent proceedings of the General Medical Council in dealing with penal cases. One of the functions of the Council is, of course, to remove from the Register those members of the profession whom it may judge to be "guilty of infamous conduct in a professional respect." The term "infamous conduct" is not defined, and the members of the profession have to rely for their interpretation of it on previous decisions of the Council. In recent years the Council has seemed disposed to take a broader view than previously of the meaning of the term, but some of the cases dealt with at the recent session can only be included in a very broad view indeed. In one of the cases to which I call attention, the charge, which, however, was not proven, was that a ship's surgeon had been on certain occasions incapable of performing his duties owing to indulgence in drink. Such conduct, if it had taken place, would, of course, be very reprehensible, but one does not know where the limit is to be drawn if it is to be adjudged "infamous in a professional respect." In another case, a medical man who had held for thirty years the position of factory inspector in Manchester, was in the habit of employing a duly qualified substitute to relieve him of some of his work. On many occasions this arrangement was made with the sanction of the Home Office, but it appears that on others such sanction was not sought, though the same gentleman was employed. There does not seem to have been any attempt at concealment, since the deputy had instructions when signing the surgeon's name, to add his own initials. There was undoubtedly a breach of Home Office rules, sufficient perhaps to warrant the Home Office in dismissing the accused. In adjudging him "guilty of infamous conduct in a professional respect," the General Medical Council has, however, taken a daring step, and one which gives rise to some anxiety among the members of the profession. If every breach of official rules is to be penalised in such drastic fashion, those occupying any Government position will have to mind their P's and Q's with extreme care.

I must not, of course, be taken as excusing conduct such as that charged against medical men in the two cases I have quoted. But not all reprehensible conduct is "infamous in a professional respect." Moreover, the present constitution of the General Medical Council is not such as to make us look with pleasure on a great increase in its disciplinary powers. The Council is not as it should be, representative of the bulk of the profession. Its members know little of the daily life, the struggles and the temptations, of the rank and file. There is no reason to suppose that the ethical standard of consultants and professors is higher than that of their more humble *confrères*, or that their conduct approaches nearer to their standard. Their temptations and sins are different, and with them, as with other mortals, there is a tendency to compound for sins they are inclined to, by damning those they have no mind to. With a reformed and representative Council, there might not be the same objections to a stretching of penal powers, but at present I believe it is fraught with danger to us all.

I am, Sir, yours truly,  
POOR, BUT HONEST PRACTITIONER.

## RESEARCH DEFENCE SOCIETY AND ANTI-VIVISECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent, "A Manchester Subscriber," has called the attention of your readers to an anti-vivisection meeting, lately held in Manchester. "It seems a pity," he says, "that the Research Defence Society cannot follow these men about with lecturers

on the other side." Let me say that the Research Defence Society has already begun that very useful part of its work. We have given about 50 lantern lectures, on the value and the necessity of experiments on animals. These lectures have been given in London and in many other places. We have two good sets of lantern slides; one of them illustrating some of the chief discoveries made in physiology and pathology (cerebral localisation, thyroid extract, diphtheria, malaria, yellow fever, sleeping sickness, Malta fever, etc.), and the other illustrating Pasteur's life and work. We have always found these lectures have been very well received, and that people are really glad to hear what our Society has to tell them. I shall be delighted to send either set of slides, with catalogue and notes, to any qualified man who will give a lecture on them. Or I will gladly give the lecture myself, if any of your readers likes to make arrangements for such a lecture in any of our large towns. But, of course, it is desirable that we should have as many lecturers as possible, and that the lecture should be given, not by a man sent down from London, but by a man who has worked for years among the people to whom he is lecturing.

I need not say that I shall be delighted to send to any of your readers the pamphlets published by the Research Defence Society, to receive names for membership, and to answer all inquiries.

The Society has already more than 2,700 members, and more than 100 associates, and is doing a lot of valuable work in a quiet sort of way.

I am, Sir, yours truly,

STEPHEN PAGET,

Hon. Secretary, Research Defence Society,  
70 Harley Street,  
London, December 9th, 1909.

## LOCAL GOVERNMENT AT KING'S LYNN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—During the past few months, as constantly during past years, the exposure has been made in your columns of the more or less complete failure of sanitary legislation in a great number of urban and rural districts throughout the country. Last week it was villages in Carnarvon, in which scandalous disregard of elementary sanitation was described; a few weeks earlier the condition of Gravesend was exposed, and this week you give the amazing story of King's Lynn. On many occasions you have allowed me to point out that in all such cases it is not fair to put the blame entirely upon the local authority. The evils and scandals usually exist, it is true, because the authority is dominated by men who are too ignorant to understand the importance of sanitation, or are influenced by sordid personal considerations. In one of your recent reports you quoted a councillor who explained, with the tacit approval of his colleagues, that they could not put the laws in force, as it might offend their friends, that was, the owners of slum property. These men are not the most to blame; the blame lies primarily upon the public, who do not turn them off, and replace them by properly qualified and independent men. No one knows so well as the medical officers of health, to whom you refer, how terrible is their position under authorities of the inferior kind. They have to stifle their conscience, and suffer constant humiliation, knowing very well they are at the mercy of their masters, have no appeal to any higher power, and no public opinion to support them. The new Housing Bill will place further duties and responsibilities upon local authorities, and although the County Council will have some small powers of supervision, I can see no chance that the new legislation, more than the old, will be followed by anything like the harvest of good results which might be expected if the mass of our citizens were imbued with the modicum of patriotism necessary for the successful working of democratic institutions, such as ours have now entirely become.

I am, Sir, yours truly,  
A YORKSHIRE M.O.H.

December 11th, 1909.

## THE HEALTH OF DUBLIN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I wonder whether the Dublin Town Council ever consider what the trade of the city loses owing to its bad sanitary reputation, which is so frequently exposed in all the medical papers, as well as in your own? It is perfectly certain that I am only one of a great number of English physicians who never fail to caution their patients as to the risks they run by residence in Dublin. Those attached to the Vice-Regal court are, of course, obliged frequently to remain in that town; but I am certain that of the wealthy tourists who now visit Ireland in increasing numbers only a comparatively small proportion linger for more than a day in Dublin. What this means to the hotel keepers and tradesmen they may perhaps know, or, if they do not know, they may easily learn. It is within their power to put on the town council men more alive to the material interests of the citizens, and even imbued with humanitarian sentiments powerful enough to stimulate them in safeguarding the health and lives of the community, and especially of the poor helpless classes committed to their charge.

I am, Sir, yours truly.

M.D., F.R.C.P.

London, W., December 11th, 1909.

## OBITUARY.

FREDERICK GRAHAM TWIGG, F.R.C.S.ED.,  
M.R.C.S.ENG., L.S.A. (of Denaby).

We regret to record the death, from pneumonia, of Dr. Frederick Graham Twigg, of Denaby Main, Sheffield, which took place on the 5th, after a short illness, at the age of 49.

One of the best known surgeons in the district, well known as an enthusiast in ambulance work, Dr. Twigg indirectly owed the illness which cut him down to the zeal he displayed in the spread of first aid knowledge.

The deceased gentleman commenced practice in the district 20 odd years ago at Mexbro', and succeeded Dr. Sykes at Denaby shortly afterwards.

He was prominently associated with the establishment of the Fullerton Accident Hospital at Denaby, where he had performed many operations. He was also identified with the Mexbro' Montagu Hospital.

## MILITARY &amp; NAVAL MEDICAL NOTES.

**CONVALESCENT HOME FOR OFFICERS AT OSBORNE.**—By command of the King, this Home is now equally open to officers of the Territorial Forces with officers of the Army and Navy and Special Reserve. The benefits accruing from this Home are inestimable, and officers owe much to His Majesty's thought and consideration.

**QUEEN ALEXANDRA MILITARY HOSPITAL.**—We understand that some change is contemplated in the accommodation at this Hospital for Sick Officers, who are at present treated in special wards in the Hospital building. It is proposed to convert a house in the grounds, detached from the Hospital, and at present occupied as a residence by the Registrar, into the officers' hospital.

**TERRITORIAL MEDICAL OFFICERS AND GENERAL HOSPITALS.**—The question recently put in Parliament on this subject by Captain Faber is of some importance. The Secretary of State for War was asked whether he could state if there was a Territorial Senior Medical Officer in London suitable to take up command of No. 1 General Hospital. The reply given by Mr. Haldane was as follows:—"This General Hospital is formed by the staff of St. Bartholomew's Hospital. The Senior Physician asked that Colonel Harrison, a distinguished medical officer who had been in the

Grenadier Guards, should be appointed Administrator, and he was accordingly gazetted on 2nd November." The Colonel Harrison alluded to only recently retired, under the age clause, from the command of the Alexandra Military Hospital, Millbank. Of his fitness for administration there can be no doubt; but, at the same time, Mr. Haldane did not directly answer Captain Faber's question, which was seeking for information whether or not a suitable Territorial Medical Officer in London was available. It must be understood that in General (Territorial) Hospitals promotion goes in the unit, and not throughout the General Hospitals.

## NOTIFICATION OF SYPHILIS—ARMY ADVISORY BOARD.

—A pamphlet, entitled, "Should syphilis be Made Notifiable," has been published by John Bale, Sons and Danielsson, which deals with the pros and contras of this difficult problem. The views of French and German doctors are given, as also the difficulties and dangers of notification, with remarks on general measures. The author's name does not appear, but nevertheless the matter in the pamphlet is worthy of perusal. A leaflet has also been printed of "Recommendations of the Army Medical Advisory Board on the Prevention of Venereal Diseases. The last two paragraphs of the leaflet comprise the chief points to which the committee commits itself. These paragraphs run as follows:—"Taking into consideration the present state of expert opinion abroad, and the opposition certain to be raised in this country should the re-enactment of a statute on the lines of the Contagious Diseases Acts be proposed, the Committee has come to the conclusion that, in the United Kingdom at any rate, an attempt to grapple with the problem of venereal disease by methods of compulsory isolation and treatment is neither practicable nor expedient. Better results are likely to be obtained by the diffusion of the knowledge of the serious consequences of these diseases, and the provision of effective treatment for both sexes under conditions to which no penal stigma is attached. If this conclusion is sound, the more necessary is it that trustworthy methods of treatment should be thoroughly understood by members of the medical profession, and rendered readily available both in military and civilian practice."

## REVIEWS OF BOOKS.

## WHO'S WHO, 1910. (a)

NEXT to *The Medical Directory*, there is probably no publication of its class that is more useful to, or more often referred to by, medical men than this annual; indeed, it may be asserted without demur that there is none other that contains the same information within covers, as this red book, with its captious title. First we have the Royal Family and all about them. We then come to an "Obituary" of all persons of distinction who have passed away during the previous year. Following this we find a list of names, addresses and biographical notices, arranged alphabetically, of persons resident in the United Kingdom, of social, political, professional, religious or literary position. If one wants to know the lineage of a duke or other titular individual; the posts occupied by this or that minister, present or past; the rank of some distinguished *litterateur*, divine or poet; or the position occupied in the medical world by a member who has climbed the ladder of fame, one will find them duly chronicled in this book. Doubtless there are a few heartburnings in the breasts of some who have not yet been accorded by the Editor a niche in "Who's Who"—albeit the book grows year by year; yet this may be said for it, that although one might occasionally stumble in its pages on a nobody (comparatively), we have never failed to find the record of names and biographies of persons of distinction in every walk of life when testing its two thousand odd pages.

(a) "Who's Who, 1910." Published by Messrs. A. and C. Black, Soho Square, London.

## THE ROYAL PRUSSIAN SPAS. (a)

The Royal Prussian Board of Domains have just published an "Album of the Spas" owned by them, in order to supply the medical profession of English-speaking countries with the necessary information regarding the spas under their control. A copy of this sumptuous production has been sent us, and we have no hesitation in stating that for the beauty of its illustrations and the wealth of its textual description, we have seen nothing to equal it in books of this class. Here we have Ems, for instance, which has been aptly called "the Queen of German Watering Places," its history, climate, waters, curative powers, diseases for which they are especially applicable, and the methods of administration fully described. Then we find the bottling for exportation of the waters, the extraction of salts, the manufacture of pastiles, and other important and interesting facts beautifully illustrated in coloured and plain plates, so that with the general information as to season, baths, inhalations, promenades, amusements, etc., nothing is left to the physician who contemplates sending a patient to necessitate inquiry, nor for the patient when he arrives at his destination. The same process is gone through regarding Langenschwalbach, Schlangenbad, Weilbach, Neiderselters, FACHNIGEN, and other less-known spas, such as Geilnau, Neundorf, Relsburgh, and Norderney. It affords us pleasure, therefore, to congratulate our *confrère* Dr. Stern, of Langenschwalbach, as editor of the work, the translator (Mr. Dan Heuser, of London), and the Royal Prussian Board of Domains on their enterprise.

## HYSTERIA AND ALLIED VASO-MOTOR CONDITIONS. (b)

Dr. SAVILL, in addition to being the author of a well-known book on clinical medicine, has published many papers and lectures on diseases of the nervous system. The present volume consists of a series of lectures on Hysteria and its Congeners. This department of medicine is an attractive one, and in the author's capable hands affords ample material for thought. He has had many years of hospital experience, and has made the most of his opportunities for collecting interesting cases. He frequently refers to the work of foreign writers, Charcot especially, and has derived benefit from their teaching. He is a good dermatologist, and often describes skin complications with considerable detail. He discusses at length the interesting question whether celibacy and unsatisfied sexual desire should be considered contributory causes of hysteria, and points out that many happily married women suffer from hysterical disorders quite as grave as those of their unmarried sisters. Moreover, this condition is not more common in religious sisterhoods than amongst communities where celibacy is not observed.

The lecture on acroparæsthesia (perverted sensations referred to the extremities), erythromelalgia, and other vaso-motor disorders, is one of the best in the collection, and will be read with much interest. We have nothing but praise for the admirable manner in which the material has been brought together, and the only suggestion we have to offer is that an index would be an advantage. The author pays a graceful compliment to his wife, Dr. Agnes Blackadder Savill, for the material help she has afforded him by many valuable criticisms and suggestions. We wish the book every success.

## INFECTED EARS. (c)

WE have carefully perused Mr. Faulder White's monograph without being in the least convinced that the methods which he so persistently and so zealously advocates possess the enormous advantages which he would have us believe. Any value that such methods might possess is very largely discounted by the want

of accurate pathological work, and by the remarkable loose clinical observation shown throughout. Take the series of cases, 1 to 20, on pages 65 to 77, in one of them is any lucid account given of the condition of the middle ear, and the only functional allusion to is that of the watch, an instrument abandoned by all scientific otologists, and which is fallacious and unreliable. Case 8 is said to have "practically no hearing," and it is stated that "auditory nerve had lost its function altogether." No means are given us of judging the truth of this assertion, no tests are offered to show that the deafness is perceptive and not conductive.

Further, there is nothing new in Mr. Faulder White's advocacy of the removal of polypi, bone granulations, diseased ossicles, etc., and every otologist has done "otectomies" (a word which seems to have the same effect upon Mr. Faulder White as "Mesopotamia" upon a more celebrated character) from the outset of his career, but the ruthless scraping out of the tympanic contents *via* the meatus, done as Mr. Faulder White recommends, is a method condemned by modern workers as contrary to the most elementary principles of surgical treatment.

One of the most remarkable statements in this book is that upon page 33, that the incus is comparatively rarely diseased, a statement so utterly against the evidence of pathological fact, that one would wonder how even Mr. Faulder White can make it.

Another curious instance of the loose clinical observation which marks the narration of cases is that which makes the author say (page 47) that an "otectomy" will give "immediate relief, even when meningitis has existed for some time, no doubt by lessening tension and securing a free discharge of blood, serum, and possibly pus." We can find, in several of the cases, evidence of aught but retained pus in the tympanic cavity, certainly none of meningitis.

Had the author lived one hundred and fifty, or even one hundred years ago, he might have been a pioneer

## DRUGS AND THE DRUG HABIT. (d)

FOR many years Dr. Sainsbury was a practical pharmacologist, and published many valuable articles on the actions of drugs. Of late, however, he seems to have devoted his attention to a somewhat different branch of the subject, and to have become what we may call a psychological pharmacologist. His "Principia Therapeutica" was an admirable work, and excited favourable attention. The volume before us professes to deal with drugs and the drug habit, but it goes somewhat further than this. The first chapter is "Historical," dating back to the early days when Jove hurled his thunderbolts and Apollo drew his bow. It traces the history of medicine downwards from its beginning in myth and fable to the present time. In the second chapter he deals with the general principles of treatment, whether by drugs or other means. He by no means confines himself within the limits of the Pharmacopœia—whether British or otherwise—but takes a broad and comprehensive view of the subject. Later on he deals with the Psychic Basis of Drug Treatment, and discusses many interesting and complex subjects. The question of drug habit and control is used chiefly as a basis, which to found many highly philosophical speculations stated clearly and lucidly, and of the greatest interest. Even when dealing with the subjects of "Imperative Suggestion" and the "Newer Therapeutics," the same high standard is everywhere maintained. The author deals with many diverse matters ranging from the influence of Greek thought and the defects of the Gothenburg system to the anthropological aspects of Nature and the virtues of koumiss.

It is a delightful book, of interest to both lay and medical readers, and is written in scholarly language beyond praise. Medical writers are as a rule not endowed with any great facility of expression, and the average "Oration" delivered before some more or less learned Corporation leaves much to be desired. Dr.

(d) "Drugs and the Drug Habit." By Harrington Sainsbury M.D., F.R.C.P. London: Methuen and Co. 1909.

(a) "Album of the Spas of the Royal Prussian Domains." Agents for Great Britain, Findlater, Mackie, Todd and Co., Canal Street, London, S.E.

(b) "Lectures on Hysteria and Allied Vaso-Motor Conditions." By Thomas Dixon Savill, M.D. London: Henry J. Glaisner. 1909.

(c) "Infected Ears (Intra-meatal Treatment)." By F. Faulder White, F.R.C.S. London: The Celtic Press. 1908.

Sainsbury has set an example of masterly diction which we can only hope may, at some future time, be emulated. We shall watch with much interest the appearance of the author's next contribution.

### THE "WELLCOME" PHOTOGRAPHIC EXPOSURE RECORD AND DIARY, 1910.

As so many members of the medical profession take an interest in photography, either for illustration of cases in the medical journals or books or as an interesting and instructive hobby, this "Photographic Record and Diary," which is published annually, has become almost a necessity for them. It certainly holds an unique position amongst photographic publications, as in no other book can be found such a wealth of expert, practical information on the essentials of photography, in such a condensed and crystallised form—not a word is wasted. Practice is the keynote throughout the book—its size prohibits theory.

Every word of its expert articles and every figure in its numerous formulæ are the results of research and actual experience. Let the photographer follow the instructions given in the article on exposure, and his exposures will be correct. Let him develop those exposures according to the methods set forth, and ideal negatives will be the inevitable result.

A very important feature is the "Wellcome" Mechanical Exposure Calculator, admitted to be the simplest efficient instrument ever introduced for the purpose. It is fastened inside the back cover of the book, and cannot be lost or mislaid. It cannot get out of order, and no refills of sensitised paper or other material are required. One turn of one scale tells the correct exposure for any subject at any time of the day or year, in any part of the world.

In the 1910 edition before us, the chapters on exposure have been carefully revised, and the list of plate factors corrected and amplified to include the latest introductions. Several new features have been added. Amongst these may be mentioned—improved methods of obtaining wide variations in colour of sulphide-toned prints; illustrations showing extensive range of colours obtainable on lantern slides by simple development; together with the latest data relative to time development at different temperatures.

The "Wellcome" Photographic Exposure Record and Diary is meant for the pocket—not the bookshelf—and it is strongly but daintily bound to stand the wear-and-tear of constant reference in field and dark-room.

For the convenience of photographers in different parts of the world three editions are issued:—(1) Northern Hemisphere (bound in light green); (2) Southern Hemisphere and Tropics (bound in dark green); (3) United States of America (bound in red).

When purchasing, care should be taken to specify which edition is required. It may be obtained of all photographic dealers and booksellers, and at all railway bookstalls. Price in British Isles, 1s.

### NEW BOOKS AND NEW EDITIONS.

The following have been received for review since the publication of our last monthly list:—

ERWARD ARNOLD (London).

A Text-Book of Medical Treatment (alphabetically arranged).

By William Caldwell, M.A., M.D. Pp. 630. Price 16s. net.

RAILLIÈRE, TINDALL AND COX (London).

Aids to Microscopic Diagnosis. (Bacterial and Parasitic Diseases.) By Ernest Blake Knox, B.A., M.D. (Dublin Univ.), D.P.H. (Honours). R.C.P.I. Pp. 156. Price, cloth, 2s. 6d. net; paper, 2s. net.

Catechism of Hematology. By R. L. Watkins, M.D. Pp. 31. Price 2s. 6d. net.

Pulmonary Tuberculosis and Sanatorium Treatment. By C. Muthu, M.D., M.R.C.S., L.R.C.P., Illustrated. Pp. 201. Price 3s. 6d. net.

JOHN BALE, SONS, AND DANIELSSON, LTD. (London).

The Diet Factor in Disease. By George Black, M.B. Edin. Pp. 91. Price 2s. net.

Tropical Medicine and Hygiene. By C. W. Daniels, M.B., M.R.C.P., and E. Wilkinson, F.R.C.S., D.P.H., etc., etc. Part I. Pp. 264. Price 7s. 6d. net.

A. AND C. BLACK (London).

Primer of Statistics. By W. Palin Elderton and Ethel M. Elderton. Pp. 86.

The Writers' and Artists' Year-Book, 1910. Price  
The Englishwoman's Year-Book and Directory, 1910. Edited by G. E. Milton. Pp. 382. Price 2s. 6d. net.

Who's Who for 1910. Pp. 2,162. Price 10s. net.

Who's Who Year-Book for 1910. Pp. 162. Price 1s. net.

CASSELL AND CO., LTD. (London).

Hypnotism and Treatment by Suggestion. By J. Milne Bramwell, M.B., O.M. Pp. 216. Price 5s. 1et.

Serums, Vaccines and Toxines in Treatment and Diagnosis. By Wm. Cecil Bosanquet, M.A., M.D. Oxon., F.R.C.P. Lond., and John W. H. Eyre, M.D., M.S., F.R.S. Edin. Second Edition, Revised and Illustrated. Pp. 362. Price 7s. 6d.

Syphilis. By Sir Jonathan Hutchinson, F.R.S., LL.D., F.R.C.S. New and Enlarged Edition. Illustrated. Pp. 583. Price 10s. 6d. net.

The Case against Christian Science. By Stephen Paget, F.R.C.S. Being Papers read at the Church Congress, Swansen, and the Annual Meeting of the Congregational Union, Sheffield. Pp. 36. Price 6d. net.

THE CLARENDON PRESS (Oxford).

Browne's Religio Medici and Digby's Observations. Pp. 183 and 44. Price 5s. net.

DUNLOP PRINTING CO. (Philadelphia).

Philadelphia General Hospital Reports. Vol. VII. 1908. Edited by Herman B. Allyn, M.D. Pp. 272.

HENRY FROWDE, AND HODDER AND STOUT (London).

Constipation and Allied Intestinal Disorders. By Arthur F. Hertz, M.A., M.D., M.R.C.P. Illustrated. Pp. 344. Price 10s. 6d. net.

Oxford Medical Publications. A System of Operative Surgery. By various Authors. Edited by F. F. Burghard, M.S. Lond., F.R.C.S. Eng. In Four Volumes. Vol. III. Illustrated. Pp. 763. Price 36s. net per volume, or £6 net per set of four volumes. (Volumes I, II, and IV. published previously).

G. GILLIES AND CO. (Glasgow).

THE YEAR-BOOK PUBLISHERS (Chicago).

The Practical Medicine Series. Edited by Gustavus P. Head, M.D. Vol. VI.—General Medicine. Edited by Frank Billings, M.S., M.D., and J. H. Salisbury, M.D. Pp. 358. Price 6s. net. Vol. VII.—Pediatrics. Edited by Isaac A. Abt, M.D., and May Michael, M.D. Orthopaedic Surgery. Edited by John Ridlow, A.M., M.D., and A. Steindler, M.D. Pp. 242. Price 5s. net. Vol. VIII.—Materia Medica and Therapeutics. Preventive Medicine, Climatology. Edited by George F. Buller, Ph.G., M.D., Henry B. Favill, A.B., M.D., Norman Bridge, A.M., M.D. Pp. 348. Price 6s. net.

HENRY J. GLAISHER (London).

Soured Milk and Pure Cultures of Lactic Acid Bacilli in the Treatment of Disease. By George Herschell, M.D. Lond. Second Edition. Pp. 72. Price 2s. 6d. net.

GOVERNMENT PRINTING OFFICE (Washington).

Index-Catalogue of the Library of the Surgeon-General's Office, United States Army. Authors and Subjects. Second Series. Vol. XIV. Q.—Ryehak. Pp. 829.

WM. GREEN AND SONS (Edinburgh and London).

Pathogeny of the Neurasthenic States. By Dr. Paul Dubois. Authorised Translation by Edward G. Richards. Pp. 61. Price 2s. net.

HAZELL, WATSON AND VINEY (London).

Hazell's Annual for 1910. Edited by Hammond Hall. Pp. 608. Preventive Hygiene. An Account of the Brussels International Conferences, 1899 and 1902. By an English Member. Third and Enlarged Edition for 1909. Pp. 31. Price 3d.

J. B. LIPPINCOTT CO. (London).

The Harvey Lectures. Delivered under the Auspices of the Harvey Society of New York, 1907-08. Pp. 266. Price 9s. net.

LONGMANS, GREEN AND CO. (London).

A Practical Guide to the Administration of Anæsthetics. By R. J. Probyn-Williams, M.D. Second Edition. Illustrated. Pp. 228. Price 4s. 6d. net.

The Essentials of Chemical Physiology, for the Use of Students. By W. D. Halliburton, M.D., LL.D., F.R.S. Seventh Edition. Illustrated. Pp. 280. Price 4s. 6d. net.

W. B. SAUNDERS COMPANY (Philadelphia).

A Text-Book of Surgical Diagnosis. By Daniel N. Eisendrath, M.D. Second Edition. Illustrated. Pp. 885. Price 28s. net.

Treatment of Diseases of Children. By Charles Gilmore Kerley, M.D. Second Edition. Pp. 629. Illustrated. Price 21s. net.

Surgery: Its Principles and Practice. Vol. V. Edited by W. W. Keen, M.D., LL.D., and J. Chalmers DaCosta, M.D. Pp. 1274. Price 30s. net.

EVELEIGH NASH (London).

Home Exercises for Health and Strength. By Filip Sylvan, M.D., Berlin. Illustrated. Pp. 122.

SIMPKIN, MARSHALL AND CO. (London).

Social Disease and its Prevention. By H. N. Robson, M.R.C.S., L.R.C.P. Second Edition. Pp. 104. Price 3s. 6d. net.

WALTER SCOTT PUBLISHING CO., LTD. (London).

Health: A Royal Road to It. By J. P. Sandlands, M.A., T.C.D. Pp. 48. Price 3d. net.

WHITE CROSS LEAGUE (London).

The Falling Birth-rate and its Significance. Notes Compiled by Lieut.-Col. H. Everitt, R.M.A. (retired), Hon. Secretary, White Cross League. Pp. 40. Price 6d.

JOHN WRIGHT AND SONS, LTD. (Bristol).

Lectures on Surgical Nursing. By E. Stanmore Bishop, F.R.C.S. Illustrated. Pp. 143. Price, Leather 3s. 6d. net. Cloth, 2s. 6d. net.

Gout: Being Part VIII. of Several Clinical Treatises on the Pathology and Therapy of Disorders of Metabolism and Nutrition. By Professor Dr. H. Strauss. Authorised Translation under the direction of Nellis Barnes Foster, M.D. Pp. 70. Price 3s. 6d. net.

Golden Rules of Anæsthesia. By R. J. Probyn-Williams, M.D. Third Edition, revised. Pp. 67. Price 1s.

Golden Rules of Dental Surgery. By Chas. W. Glassington, M.R.C.S., L.D.S. Edin. Third Edition. Pp. 72. Price 1s.  
 Urgent Surgery. By Felix Lejars. Translated from the Sixth French Edition by William S. Dickie, F.R.C.S. Vol. 1. 25s. net.  
 Wright's Improved Physicians' and Surgeons' and Consultants' Visiting List. Compiled by Robert Simpson, L.R.C.P., L.B.C.S., Form A, 1s.10. Price 5s.

## MEDICAL NEWS IN BRIEF

### Medical Graduates' College and Polytechnic.

At a conversazione, held on December 10th, in the Medical Graduates' College and Polyclinic, 22 Chenies Street, Gower Street, W.C., Dr. Bashford gave a terse, vivid and plain demonstration on recent cancer research, showing that continuous mechanical irritation is the preliminary cause of cancer, then that the disease is found in Asia, Africa, and America as well as in Europe, and in animals, apart from man (birds, fishes, cats, reptiles, etc.). This was followed by an exhibition of sections showing that cancer cells grow by the help of the connective tissue cells of the host forming a scaffolding for their support, and that if an emulsion of living skin cells of the same animal be first injected and cancer cells then inoculated the malignant disease dies off, the connective tissue cells not lending their aid, apparently being inhibited by the skin injection. Diagrams showing the tendency to cure under some conditions, and the relation of age to the disease, were also shown.

There was also shown during the evening specimens of radium by Dr. W. Hampson, viz. :—

1. Pitch blende, from which uranium and radium are extracted.
2. Deposit from Bath waters, containing radium-bearing substances.
3. Radium rays sparking against zinc blende.
4. Zinc sulphide rendered luminous by radium.
5. Platino-cyanide and Willemite rendered luminous by radium.
6. Electroscopie discharged by approaching it with radium.
7. A radium clock, so-called, where the leaves of an electroscopie are made to diverge with radium in vacuo, and when the leaves rise sufficiently to touch the metal points on the sides of glass container they are discharged and collapse, and the process recommences.

### Medical Students of the R.U.I.—Action of the Colleges of Physicians and Surgeons.

THE Royal College of Physicians of Ireland, and the Royal College of Surgeons in Ireland, have had under consideration the position of medical students who have taken out some of their examinations in the late Royal University of Ireland, and who may desire to carry on their studies and to take their qualifications under the Conjoint Scheme for Ireland. The Royal Colleges have decided that candidates for examination under the Conjoint Scheme who have obtained exemption from examination in certain subjects, by reason of their having, prior to the 1st November, 1909, passed in such subjects at some University or other licensing body, be excused from payment of half the fees for the examination or division of examination from which they have been exempted.

### The Weber-Parkes Prize and Medals.

THE Royal College of Physicians of London announce that the next award under this foundation will be made in 1912, and the Adjudicators have selected as the subject of the essay for that occasion :— "The influence of mixed and secondary infections upon Pulmonary Tuberculosis in Man, and the measures, preventive and curative, for dealing with them." All essays, together with any preparations made in illustration of them, must be transmitted to the Registrar of the College (Dr. J. A. Ormerod) during the last week of May, 1912, in accordance with the regulations relating thereto, copies of which will

be forwarded from the College on application. The award will be made at some time previous to the 18th of October in that year, on which day the prize and medals will be presented to the winners.

### Proposed Open-Air Sanatorium for Working Class Consumptives.

A HIGHLY successful and well-attended meeting was held recently at Hillingdon Court, Uxbridge, in support of a scheme to provide an open-air sanatorium for working-class consumptives in Middlesex. The gathering was addressed by Dr. J. L. Lock, medical officer of health of Uxbridge Urban District; Dr. A. Charpentier, medical officer of health of the Uxbridge Rural District; and Dr. J. J. Perkins, honorary secretary, National Association for the Prevention of Consumption. A resolution was ultimately adopted supporting the scheme. Part of the money is to be raised by inaugurating a 20,000 Crowns Fund, subscriptions to which will be invited from all classes. When this sum has been collected, and a beginning made, an appeal will be issued for larger subscriptions, and other sources of money tapped. Till such time as a trust is formed local representatives will be appointed to receive subscriptions, Mr. Andrew Clark, F.R.C.S., being the one chosen for the Uxbridge district. It is intended to erect buildings which, when completed, will accommodate 10 patients; and it is believed that by spending as little as possible on buildings (which will be on the pavilion plan) the total cost will not be more than £100 per bed. A start will be made as soon as the 20,000 crowns (£5,000) have been collected, it being hoped to provide 30 beds, together with the administrative offices, for this sum. As funds permit further accommodation will be added. The beds are to be for the use of all suitable Middlesex cases whose cost of maintenance is guaranteed privately or by the local authorities or other bodies, or persons maintaining beds. The total cost per patient, it is considered, ought not to exceed 25s. per week in a sanatorium with 100 beds.

### Cardiff Medical Students' Club.

THE annual smoking concert of the Cardiff Medical Students' Club was recently held at the Royal Hotel. There was an attendance numbering 60 medical students and several medical practitioners and professors, including Professor Hepburn, Professor Haycraft, Dr. Charles Vachell, Dr. Crawford Treasure, Dr. Cyril Lewis, Dr. Arthur, Dr. Naunton Morgan, and Dr. Scholberg. Mr. Wm. Sheen was installed the President of the club for the ensuing year in succession to Dr. Maclean.

### Royal College of Surgeons, Edinburgh.

At the meeting of the College, held on the 11th inst., the following gentlemen were elected Fellows :—

Edmund C. Bevers, M.B., M.R.C.S.Eng., L.R.C.P. Lond., Oxford; Harry H. Bywater, M.B., Ch.B., Preston; Arthur J. Evans, M.R.C.S.Eng., L.R.C.P. Lond., Liverpool; William A. Fairclough, M.B., M.R.C.S.Eng., L.R.C.P. Lond., Dunedin; William Girdwood, M.B., Ch.B., D.P.H., Transkei; John P. Granger, L.R.C.S.I., Glasgow; Rowland H. Harris, L.R.C.S.E., Battle Creek, Michigan; Robert A. D. Hird, M.D., M.R.C.S.Eng., L.R.C.P. Lond., Birmingham; James Husband, M.B., Ch.B., Capt., I.M.S.; Arthur W. B. Livesay, M.B., C.M., Staff Surgeon, R.N.; Thomas R. McKenna, L.R.C.S.E., Edinburgh; Henry J. McLean, M.B., Ch.B., Wellington, New Zealand; Samuel W. McLellan, M.D., West Kirby; John Morris, M.B., Ch.B., Llanymynech; William J. Morton, M.D., L.R.C.S.E., Invernell, New South Wales; Anath Nath Palit, L.R.C.S.E., London, W.; James Raffan, M.D., Aberdeen; James M. Renton, M.B., Ch.B., Glasgow; James Russell, M.B., Ch.B., Glasgow; Clinton P. Sapsford, M.B., Ch.M., Toowong, Queensland; Charles J. Smith, M.B., Ch.B., Edinburgh; George M. Smith, M.B., Ch.B., Perth; John A. M. Smith, M.B., Ch.B., Naogoan, E. Bengal; Walter Taylor, M.B., M.R.C.S.Eng., L.R.C.P. Lond., Ontario, and Owen H. Williams, M.B., Ch.B., Liverpool.

## SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

*Specially compiled for THE MEDICAL PRESS AND CIRCULAR.*

[SPECIALLY REPORTED FOR THIS JOURNAL.]

**Removal of an Embolus from the Common Iliac Artery; Restoration of the Circulation.**—Murphy (*Ann. Med. Review*, October, 1909).—In treating the case of a woman whose left lower limb was undergoing dry gangrene, extending up to four inches below Poupart's ligament, decided to remove the aseptic embolus that was occluding the iliac artery. The patient had a double mitral murmur. Two and a half inches of the femoral artery was exposed, and two provisional catgut sutures were passed round it, but not tied. These were used to elevate the artery, which was incised in its long axis for one inch, and found completely thrombosed. With a delicate forceps,  $1\frac{1}{2}$  inches of clot was drawn from below. Fresh arterial blood came from below. A finger was placed on the lower end of the artery inside the ligature loop, so as to compress the vessel and stop the flow of blood. The operator failed to get fresh blood from the upper end of the artery by using a delicate forceps, a spoon, a No. 6 soft catheter introduced  $7\frac{1}{2}$  inches. A little arterial blood followed the withdrawal of a urethral catheter, which had been passed up 19 inches. A uterine sound was then introduced. At a distance of  $7\frac{1}{2}$  inches it met with a resistance. It was forced  $\frac{1}{2}$  inch further, and on withdrawal much grumous, thrombotic debris came, but no arterial blood. It was pushed a little further on, and met a firm resistance. No blood followed its withdrawal. On the third attempt, with a little additional force, it seemed to pass at  $8\frac{1}{2}$  inches into a free space. This was followed by an intense arterial flow, carrying embolic debris with all the pressure and quantity of the normal femoral artery. Hæmorrhage was controlled as on the distal side. With a fine silk suture on a full curved conjunctival needle, rapid, continuous suture of the arterial incision was made. After removal to bed, the patient complained of pain and burning in the toes, the first sensation in those parts since the onset. At the line of demarcation the circulation improved immediately, and became well established in the small vessels at the line of amputation. The writer considers that aspiration through a catheter is a better means of removing the plug than the means he adopted. Incision into the artery at the seat of arrest of the embolus, if it has been there any time, is not advisable, as the intima is roughened, and there is a tendency to subsequent thrombosis. S.

**Relief of Urinary and Genital Conditions through Surgery of the Seminal Vesicles.**—Eugene Fuller (*Med. Record*, October 30th, 1909) describes his method of operating on the seminal vesicles, and the result he has obtained in 126 cases. The incision consists of three cuts—two longitudinal converging cuts along the ischium on each side, connected in front by a transverse cut  $\frac{3}{4}$  in. anterior to the margin of the anus. The lateral and then the anterior cut is deepened, the left forefinger being inserted into the rectum as a guide. The knife is discarded, and the right forefinger is employed in the deep lymph space to separate the rectal wall from the prostate and seminal vesicles, the left forefinger being retained in the rectum until the separation is complete. A long grooved director is then passed until the end of the instrument reaches the apex of one seminal vesicle, and lies just under the right finger-tip. The right finger is then withdrawn, and the seminal vesicle is freely laid open by a scalpel passed along the groove of the director (throughout the operation the patient is in the knee-breast position with the knees well separated). The granulation tissue in the cavities thus opened may be scraped away with the finger-nail or curetted if necessary. The cavities of the seminal vesicles are separately packed with gauze, and two soft drainage tubes are placed between the gauze packing and the rectal

wall. The incision is closed except where the gauze and drainage tubes project. No subsequent irrigation is necessary. This operation is not suitable for tubercular cases; 7 of the 15 unsatisfactory results were in tubercular cases. The author divides his cases into four classes, according to the predominant symptoms displayed by the patient. These are urinary, genital, nervous and mental, and rheumatic (gonorrhœal rheumatism). No death resulted in the 126 cases operated on, and all except 10 were either cured or greatly benefited. S.

**Rupture of the Uterus during Labour.**—Lobenstine (*Amer. Journ. of Obst.*, LX., 5). In a series of 60,000 cases, 46 cases of complete rupture of the uterus and 29 of incomplete rupture, and three of rupture of the vaginal vault occurred at the Lying-in Hospital, New York. In the series there were 44 cases of complete and 11 incomplete amongst multiparæ, and five complete and 18 incomplete amongst primiparæ. The chief reasons for the greater frequency in multiparæ of complete rupture are: the general health of multiparæ amongst the poor is not as good as among women who are pregnant for the first time. In a considerable number of women who have borne children the uterine musculature has been weakened by inflammation, by scars of former incomplete tears or operations. Pelvic contractions are responsible for a very large number of complete ruptures, chiefly generally contracted pelves. Mechanism of spontaneous rupture: the uterus becomes differentiated into two definite segments as the process continues; the lower zone is so thinned out, especially when the site of a chronic inflammation, that it finally is forced to yield, the imprisonment of the lower portion of the cervix, between the presenting part, especially the head and the pelvic brim, will account very largely for the spontaneous ruptures. In those cases in which the cervix does not become imprisoned but is drawn up over the presenting part, the vaginal vault is ultimately put to such a strain that a rupture occurs. The round and broad ligaments act as real supports to the lower uterine zone when it becomes dangerously thinned. When rupture occurs, if the child is entirely outside the uterus, the latter may be felt directly behind the symphysis or over to one side of the false pelvis. The author does not believe that the uterus is always fairly contracted, but is only so in the milder grades of trauma. The uterus has more often been large, flabby, and baggy. Incomplete ruptures of the uterus occur less often than the complete; they may occur in any part of the uterus. The most common type is longitudinal through one side of the cervix, through the lateral vaginal fornix, and up into the broad ligament. The next most common type has been a transverse one through the cervix into the utero-vesical space. The rapid artificial dilatation of the cervix is undoubtedly the most common cause of incomplete rupture. In the 29 cases of the series 13 were cases of placenta prævia, and the laceration due to the dilatation or the extraction of the after-coming head. Six cases were due to rapid dilatation and extraction for eclampsia, in five cases the rupture was due to a hasty delivery in the presence of a violent accidental hæmorrhage. In only five cases did the rupture appear to be spontaneous. The most frequent cause of spontaneous rupture is old scar tissue in the cervix or vaginal vault. In the 46 cases of complete rupture there were 34 deaths; in the 29 cases of incomplete rupture there were eight deaths. The foetal mortality of complete rupture was 83 per cent., and of incomplete rupture 52 per cent. The author believes the best results will be obtained from laparotomy, except in clean cases and ones with marked shock. F.

## NOTES AND COMMENTS.

**The Suffragette Executive by Mrs. Leigh, the Forced-Feeding Suffragette, has fallen to the Trial.**

THE action brought against the ground. After a patient trial, the jury, without leaving the box, found a verdict in favour of the defendants, Mr. Herbert Gladstone, the Home Secretary, the Governor of Winston Gaol, Birmingham, and the medical officer of the same prison. The facts of the case are simple enough. The lady in question had already been five times previously convicted for breaches of the law. The first occasion was in March, 1907, when she was sentenced to a month's imprisonment, and the second for two months. In October, 1908, she was released after undergoing a few 'ays' detention for a three months' sentence. On the fourth she was discharged after four days of a 3 months' sentence, apparently because she refused food. In September last, Mrs. Leigh was sentenced to four months' imprisonment, with hard labour, on account of riotous conduct in connection with a meeting at Bingley Hall, Birmingham. From a neighbouring housetop she had bombarded the wall with stones and ginger-beer bottles, and, when that "ammunition" was exhausted, with slates loosened by means of a hatchet. She was dislodged by means of a fire-engine hose, and subsequently convicted and sent to gaol, where she refused food. She was thereupon forcibly fed by means of a soft tube and a funnel, the tube being passed through the nose.

**"Deplorable and Suicidal" Tactics.**

As the prisoner resisted the feeding tooth-and-nail, she naturally found it a somewhat distressing process. At the same time, it must be remembered that forcible feeding is used in asylums and gaols in all cases where food is refused by "refractories." Why should the suffragette be an exception to the rule? Were it to become a recognised proceeding to release prisoners who refused food for a few days, our streets would soon be full of discharged criminals. Indeed, it almost looks as if Mrs. Leigh had presumed on the strength of her previous experience, when a resolute refusal of prison fare for a few days saved her two months' imprisonment. The medical men who gave evidence at the trial said nothing to shake the accepted view that if prisoners refuse food, the right and proper thing is to feed them by means of a soft tube, if necessary, passed through the nose. The doctrine of the plaintiff is, apparently, that any criminal act may be committed by way of protest against some fancied political grievance, but that subsequent punishment must be that awarded to purely political offences. Such a claim is monstrous, and, if accepted, would be speedily subversive of common law and order.

Were the followers of other causes to adopt the extreme, or—as they have been aptly termed—the "deplorable and suicidal" tactics of the suffragettes, the conditions of public life would speedily become unbearable.

**The Beit Fellowships.**

THE first ten elections for the Beit Memorial Fellowships of Medical Research will be made on March 1st next. Although the candidates must be, as a rule, graduates of a British university, it is, nevertheless, possible, under exceptional circumstances, for any holder of a registrable British diploma to become eligible. The prospect of £250 for three years may make all the difference to some poverty-stricken enthusiast whose pocket is as empty of cash as his brain and heart are full of great things. Beyond the small annual grants given by the British Medical Association and a few scattered university research scholarships and fellowships, medical science has no endowment worthy of the name. The view has often been advanced in the columns of THE MEDICAL PRESS AND CIRCULAR that the duty should be undertaken by the State in the interests of the nation. Pending such recognition, the gratitude of everyone must be rendered to the millionaire citizens who have voluntarily allotted to the purpose a share of their vast possessions. Viewed in the cold light of logical analysis, it seems only right that men who have acquired great wealth amid the security of an empire should restore some of the accumulation in order to advance the interests of their fellow citizens. That, however, is not our experience with most of the owners of wealth in the United Kingdom, otherwise the University of London and medical science would not have had to wait for the Beits to set the ball rolling.

**Christmas and Children.**

WHILE the children of Christendom are turning their thoughts merrily towards Christmas, with its manifold joys and delights, medical men, on the other hand, are seeing the tragic side of the picture. In spite of the Children Act of last year, appalling cases still appear in the coroners' courts. In one case, a helpless infant of eight weeks of age was crying and troublesome; the mother, a labourer's wife, sought the assistance of a neighbour, who kindly, but unwisely, obtained poppy heads, and, having made a decoction therefrom, administered the same to the babe, with the naturally fatal result. It is to be regretted in these cases that poppies are only in Part II. of the schedule of the Poisons Act, which simply means that they must be labelled "poppies," have the word "poison" on

them, and the name and address of the seller. Still, the word "poison" should put ninety-nine people out of a hundred on their guard when offering such a decoction to an infant. We can only assume that the woman in question was the hundredth. In another case, a child died shortly after the mother had removed it from the care of a woman to whom she had been paying six shillings a week for the infant's keep. As a matter of simple statement, the woman who had received the child to nurse was not registered, and said she did not know it was necessary under the Children Act, 1908, to be registered before receiving even one child. This fact regarding the necessity for registration cannot be too widely known, as also the section making it an offence to permit children to be in a room where the fire is unguarded. This is the first Christmas since the Act came into force, and it is to be hoped that it will materially decrease the number of avoidable tragedies in child life.

## LEADING ARTICLES.

### THE BEIT MEDICAL RESEARCH ENDOWMENT.

ONE of the great present-day needs of Medical Science is endowment, which is vital to her sustenance and growth as food, water and air to a vertebrate mammal. For various reasons the State has not hitherto recognised its responsibility in that direction, possible because, in the face of many urgent and peremptory claims upon the public exchequer, it is natural to overlook those that are not vehemently advanced and for which the return is indirect and often difficult to trace. For all that, it may be questioned whether there is any branch of human intellectual activity which would yield a greater harvest to mankind in response to a wise expenditure of capital—otherwise "endowment"—than that of medical research. In the present day, when the various sciences have reached a high pitch of development, the necessity is more than obvious of elaborate apparatus, of extensive and well-equipped laboratories, of trained assistants and workers, and of a constant expenditure of money in accessories and incidentals of various kinds. Under these circumstances, the news that a rich endowment has suddenly been bestowed upon medical science will be hailed with genuine delight by the many men whose lives are devoted to the single-hearted search for the truths that still lie hidden in that great field of human activity. On December 16th, 1909, it was formally announced that the Senate of the University of London had received a munificent benefaction in the interests of medical research. The origin of the gift was a legacy of £50,000, left by the late Mr. Alfred Beit, to found an "Institute of Medical Sciences." As the foundation of that institution was found to be, for various reasons, impossible, Mr. Otto Beit, the brother of the testator, decided to increase the sum mentioned to £215,000, so as to yield an annual income of about £7,500. This Fund, which is to be named "The Beit Memorial Fellowships for Medical Research," is to be devoted entirely to the furthering of medical research work in all its branches. With that object, a sum of £250 a year for three years is

to be granted "to any man or woman of European descent, graduate of any approved university within the Empire, who is elected to a fellowship." The elections are made by an advisory board of not less than five nor more than seven persons. The first list consists of Sir T. Clifford Allbutt, Dr. J. Rose Bradford, Dr. James Kingston Fowler, Dr. C. J. Martin, Professor William Osler, and Professor F. H. Starling. This list of names is well chosen, and guarantees that the elections will be made with catholic fairness and without a disproportionate regard to the academic influence. In some ways, the tendency to look solely to the schools for fresh scientific discoveries is to be deprecated. It has happened again and again that a great advance has resulted from the chance of a happy accident, and has come from the obscure and humble worker rather than from the universities. At the same time, the value of collective comparison and of well-informed investigation is obvious, especially when reinforced by the aid of modern appliances. It will be of interest in this connection to note from what quarter the discovery of the origin or the prevention or the cure of cancer will eventually emanate, whether from the independent observer or from the richly-endowed laboratory. From this point of view it is satisfactory to note that some modification is to be made in the original statement contained in Mr. Otto Beit's letter to the Senate, in which it is stated that the fellowships will be conferred upon graduates of universities of the British Empire. The deed of foundation contains a provision which admits qualified non-graduate medical men under certain conditions. It runs as follows:—"(11) Provided always that in certain cases the trustees may, if the advisory board so recommends, accept the possession by a Fellow at the date of election of a medical diploma registrable in the United Kingdom as a qualification for election to a fellowship, in view of his, or her, having taken such degree, or passed such examination." No time is to be lost in putting the scheme into effect, for the first elections are to be made in March, 1910, and subsequently on January 1st of each year. A list is published of recognised places where research work may be conducted, and powers are given to the trustees to recognise other places approved by the advisory committee. On the whole, the details of the Fund appear to have been carefully and wisely considered as befits a scheme of so great a national importance. The wealth of great philanthropists anxious to relieve the sufferings of their fellow creatures could hardly be more logically bestowed than in endowing the work of that science whose mission is to relieve and prevent pain, and as far as may be to promote health and banish disease. The contrast between the superabundance that is able to make so royal a gift and the poverty of the average medical research worker is one to make the philosopher think. None the less, the medical profession of the British Empire, no less than the people of that great empire, have to thank the two brothers, Alfred and Otto Beit, for a gift that is calculated to advance the interests of humanity throughout the world for generations yet unborn.

## CURRENT TOPICS.

### Christmas Fare.

THE fact that Christmas comes but once a year has been the excuse from time immemorial for an extra supply of good fare. Thanks to the robust constitution that marks the average Britisher, he is able to play a good knife and fork without fear of an aftermath of digestive troubles. The same thing is happily true of the average wholesome children of the United Kingdom, who are able to stuff themselves with good things much in the fashion that a turkey is stuffed with chestnuts and sausage-meat. Yet your plump, red-cheeked, lively little boys and girls rarely do themselves any great harm by feasting thus. The fact is, that English fare at Christmas is, above all things, in its essence, solid, wholesome, nourishing and, on the whole, digestible. It is only the weaklings who are likely to be harmed thereby, children who are habitually overfed or improperly fed, and whose pale faces testify to the want of fresh air and exercise and to daily indulgence in sweets and rich food. The verdict of many centuries has been given unanimously in favour of turkey and plum-pudding for the Christmas dinner, and they are likely to hold the field against all comers for many a century to follow. By the way, without wishing to cast a gloom over a merry season, one may speculate in passing what sort of fare vegetarians place on their Christmas board. Is it possible that some of them yield to the temptations of ordinary Christmas fare? Picture a vegetarian in the Tropics on Christmas Day refusing a slice of roast turkey on principle. Could the concrete pathos of a Shakespearian tragedy summon to our imagination a more heartrending spectacle than that? History does not relate whether the temptations of St. Anthony included a real good Christmas dinner. May all our readers—young and old—be tempted in that wise, in the living present, that is to say, on December 25th, 1909—and may they yield the point gracefully and plentifully.

### Another Successful Action for Oyster Typhoid.

LAST week we noted a case in which damages were given for enteric fever contracted from oysters. Since that occasion another action in the King's Bench Division before the Lord Chief Justice seems to supply an instance in which typhoid fever was traced with almost complete scientific precision to contaminated oysters. Two naval lieutenants partook of raw oysters when dining at a Chatham hotel. Within the usual time they both fell ill of typhoid fever. One died; the survivor went through the illness at the house of his brother, Dr. Cardale. As soon as suspicious symptoms showed themselves the diagnosis was confirmed by Vidal's test. It was proved that the oysters came from the Medway, and that notices had been posted warning the public that owing to the prevalence of typhoid fever in Chatham, it was not safe to eat shell fish from the river unless boiled. There were infected oyster beds in the Medway which had been closed by the Fishery Commission. All the other cases of typhoid at Chatham had been traced to cockles only. It was alleged, in course of the defence, that the plaintiff

having seen the notices ought himself to have been on his guard. It seemed impossible to dispute the fact that the poison was conveyed by the oysters. With the question of the legal liability of the hotel keeper we have at present nothing to do. The jury gave a verdict for the plaintiff with substantial damages, but as a stay of execution was granted on the usual terms, it is of course not at all certain that the verdict will not, in the end, be overthrown.

### The Quality of Milk.

THE Armstrong College has recently issued a report on milk, which, although it states no new facts, gives a solid scientific foundation to current knowledge of the variableness of milk in the matter of its constituent butter fats and other solids. It has been proved that the quality of the milk yielded by a cow from time to time depends very largely upon the nervous condition of the animal. Transient excitement may cause shortage of fat, which tranquillity will at once redress. This fact renders evident the possible fallacy in attempting to vindicate a farmer by milking a cow in presence of a prosecuting authority, and analysing the quality of the yield. It also, on the other hand, suggests a plausible defence in cases in which the milk may really have been deliberately sophisticated. The quality of the milk of the individual cow is liable to vary within very wide limits, from other causes mostly beyond control. The quality does not seem to be, save in the smallest degree, controlled by diet; the food affects the quantity almost alone. Cows that are milked frequently yield more fat than those left for longer periods; and it is found that when cows are milked three times instead of twice a day the extra quality of the milk compensates for the added labour. Jersey cattle gain great praise for the quality of their milk, and it is suggested that a good proportion of this breed should be included in all herds. The desirability of mixing the whole of the milk from the herd before putting it on the market seems strongly suggested by consideration of all these facts.

### The Endowment of Research.

IN his address at the Imperial College of Science, on Thursday last, Professor Sedgwick, in language almost identical with that of our leader of November 24th, explained and deplored the attitude of the public and the Government towards the workers in pure science—those who pursue knowledge for its own sake, without reference to its practical application, being urged on by what has been called a "Divine curiosity." Professor Sedgwick pointed out that the indifference with which the poor researcher is regarded by the people is shown by the almost entire absence of support on the part of Government, £4,000 a year given to the Royal Society representing the total national outlay in this direction. Professor Sedgwick then went on to discuss the problem also broached in our article—the problem how best to help workers to pursue lines of research for which they have displayed fitness. Without trial it is impossible to ascertain whether a man possesses an aptitude for scientific investigation; and Professor Sedgwick suggested the establishment of studentships in

considerable numbers, from the holders of which those that showed the necessary gift could be selected. He pointed out how necessary it would be that those who failed after being encouraged to try should be compensated, or provided with an outlet to find work in practical life. Professor Sedgwick finally pointed out that there was another way in which the difficulty could be met, and that was the way adopted by the founders of the Imperial College—namely, by the combination of a school of science with a school of technology.

### The Health of the Army.

THE Army Medical Department, of which Lieut.-General Sir Alfred Keogh is Director-General, is to be congratulated on the highly satisfactory character of their reports on the health of the troops during 1908. The death-rate for the year compares favourably with the rate among the male civil population of similar ages. The reduction in disease is clearly shown to be due to general all-round improvement, and not to any one specific cause. Some effect must doubtless have been produced by the marked decline in alcoholism, due to the efforts of temperance reformers. A steady improvement in the health of the troops has, however, gone on since 1902, when the hurtful effects of the South African campaign began to pass off. Since that year the sick-rate figures have been reduced by nearly one-half, whilst the wastage through deaths and discharges has been lessened to an equally remarkable degree; and a marked diminution in the number of invalids sent home has also been noted. The greater care now exercised in recruiting, men of questionable physique being rejected, has no doubt had a share in bringing about the improvements noted. But the results must be in the main ascribed to changes in administration, improved methods of treatment, and improvement in sanitation, in the wide sense of the word.

### The "Medical Directory" for 1910.

THE *Medical Directory*, issued by Messrs. J. and A. Churchill, is one of the best-known books in the profession. To say that it should be on every medical practitioner's study table—echoing a familiar phrase of the reviewers—is superfluous, because in the vast proportion of cases it already occupies that position. The present volume represents the sixty-sixth annual issue of this standard work. Those of our readers who may have come across the first few issues know the contrast between the diminutive issues of sixty years or so ago and the portly, handsome volume of to-day. This year there are several alterations in the editorial matter. The numerical summary of the medical profession, for instance, is extended, and in its present form offers a handy analysis under the headings of London, provinces, and the various kingdoms. The total numbers for 1910 amount to 40,558, as against 39,992 in 1909. The increase of 566 on the preceding year, which in its turn registered an increase of 289, does not by any means point to any material lessening of the overcrowding of professional ranks, even when full allowance is made for the increase of national population. Another novel feature is the publication of an excellent summary of the chief facts of British health resorts, occupying some fifteen

pages. This section should be useful to medical men as a ready means of reference. There are also some improvements in the lists of hospitals and in other directions. The price of Churchill's *Directory*, it may be noted, remains unchanged. We have pleasure in wishing this old friend prolonged life and prosperity.

### Irish Hospitals and English Nurses.

WE have often commented on the unfairness shown toward Irish and Scottish diplomates and fellows in the conditions of appointment to the medical staffs of many hospitals in England. The Irish and Scottish qualifications are in no way inferior to the English, and it is a foolish and discreditable prejudice which attempts to limit the field of competition. We regret to notice that in Ireland there are signs of a similar exclusiveness—not, it is true, as regards the appointment of medical men, but as regards the appointment of nurses to important positions. This exclusiveness is not, we are glad to say, exhibited by the hospital authorities; but, on at least two occasions lately, when an English-trained nurse was appointed to the matronship of a Dublin hospital, there has been a certain amount of popular clamour. A few weeks ago, after very careful consideration, the Board of one of the Dublin hospitals elected to the matronship of their institution a lady trained at St. Thomas's, who was, in their opinion, the best fitted for the post of the candidates who presented themselves. To this action exception has been taken in various unimportant quarters, and the Dublin Corporation, as a contributor to the hospital funds, has demanded an explanation. One would expect that the Corporation would find enough scope for its energies in its proper affairs, but instead of attending to the health of the city, it prefers to question the actions of a careful and successful board of governors. The folly of the policy to which the Corporation apparently gives its support must be obvious to all. It is the interest of the hospital, as of any other concern, to obtain the best officials it can. But, apart from this, it must be remembered that an enormous number of Irish nurses earn their bread in England, where they are eligible for, and obtain, many of the best appointments. If English nurses are debarred from Irish appointments, retaliation must be expected.

### The Ethics of Anti-Vaccination.

MR. POMEROY's evidence in the recent action, together with his letter, which we print to-day, forms a fairly complete exposition of the intellectual calibre, and the mental condition, of the typical anti-vaccinationist and anti-vivisectionist. The psychology of the class of which Mr. Pomeroy is a type, and the ætiology of the state of obsession which characterises them, have been fully discussed, and are sufficiently understood. These people are entirely ignorant of the fundamental facts of science necessary for the understanding of the questions with which they interfere, and are insensible to every argument that clashes with their fixed ideas. Mr. Pomeroy was not called upon to explain how it is that doctors vaccinate their own children; but the fact that the profession throughout the civilised world—those who earn money by the operation, and those into whose work it never

comes—offer that concrete bit of evidence as to their perfect faith in the harmlessness and efficacy of vaccination, ought to have convincing weight with people who have not had the scientific education needed in forming an independent judgment for themselves. To Mr. Pomeroy, vaccination is synonymous with syphilitic inoculation, and the only question for him is, whether the "fee-hunters are too stupid to understand the real nature of cow-pox (also identical, it seems, with syphilis), or whether the desire for fees prevents them from seeing this"; and he takes the latter view. Pity for Mr. Pomeroy, and his class would alone prevent the laughter these wild utterances might provoke, even if the thought of the tragic results of the propaganda to which they devote themselves did not put a check upon mirth. The widespread distrust of medical science to which the persistent work of such fanaticism gives rise among the ignorant of all classes, drives vast numbers into the hands of fraudulent quacks, or leads them to pin their faith on bogus remedies. The result is, the infliction of an incalculable amount of easily-preventable misery, and the deaths of many people from organic diseases amenable to scientific treatment, but allowed to assume a mortal phase whilst reliance is being placed upon gross quackery in one form or another.

## PERSONAL.

THE QUEEN has sent a present of game to the Chelsea Hospital for Women.

THE PRINCE OF WALES, on December 13th, presided at a meeting of the General Council of King Edward's Hospital Fund for London, which was held at Marlborough House.

THE PRINCESS OF WALES has sent a gift of pheasants to the British Homes and Hospital for Incurables at Streatham.

FIELD-MARSHAL THE DUKE OF CONNAUGHT has been pleased to appoint Sir Alfred Downing Fripp, K.C.V.O., to be Surgeon in Ordinary to his Royal Highness.

MR. T. E. GORDON, F.R.C.S.I., has been elected Surgeon to the Orthopaedic Hospital, Dublin.

MR. ROBERT J. HARVEY, F.R.C.S.I., has been elected Surgeon to the Richmond Hospital, Dublin, in place of the late Sir William Thomson, C.B.

DR. J. L. MAXWELL presided at a breakfast given by the Society for the Suppression of Opium Smoking at the Hotel Cecil, on December 20th.

SIR ARTHUR CONAN DOYLE has been appointed president of the newly-formed branch of the Research Defence Society at Brighton.

DR. SALTER, who contested the last Parliamentary election in Bermondsey in the Socialist interest, has withdrawn from his candidature for the General Election.

THE Public Control Committee of the London County Council proposes to invoke the aid of the Lord Chancellor in the case of the coroner of the Central District of London (Dr. G. Danford Thomas), who, owing to deafness and other illness has been unable to perform his duties for some time.

THE LORD MAYOR OF LONDON presided at the Mansion House on December 17th, for the annual general meeting of the constituents of the Metropolitan Hospital Sunday Fund.

LORD CREWE (Chairman of the Governors) distributed the diplomas, medals and prizes to the successful students at the Imperial College of Science on December 16th.

MR. OTTO BEIT has supplemented the £50,000 given by his late brother Alfred by a sum of £165,000 for medical research.

MR. GEORGE CROCKER, the son of a Californian railway financier, who left an estate of £6,000,000, has given to Columbia University a fund estimated at £300,000 for the investigation of cancer. Mr. Crocker and his wife were both victims of that disease.

LORD ROSEBURY performed the ceremony of opening the reconstructed hall and museum at the College of Surgeons of Edinburgh on December 14th.

THE Nobel prize in medicine has been awarded to Professor Theodor Kocher, who has gained a world-wide reputation in connection with the surgery of the thyroid gland. Professor Wilhelm Ostwald, of Leipsic, has gained the prize in chemistry, and the prize for physics has been divided between Mr. Marconi and Professor Karl Braun, of Strassburg.

PROFESSOR KOCHER, who has been awarded the Nobel prize for medicine, has announced his intention of giving half to the Red Cross Hospital at Berne and the rest to the poorer medical students of the same place.

WE regret to record the death, on December 14th, of Sir Alfred Jones, K.C.M.G., who, though not a medical man, was a very great friend to medicine, and especially tropical medicine, his instrumentality having founded the Liverpool School of that branch of science.

THE late Sir Alfred Jones left the whole of his estate, subject to certain family and business legacies, to charity, and more especially to further the study of tropical medicine.

THE following appointments and elections have been made at a meeting of the Council of the Royal College of Surgeons:—Mr. J. F. Colyer, M.R.C.S., L.D.S. Eng., Honorary Curator of the Odontological Collection in the museum; Mr. H. F. Waterhouse, F.R.C.S., Surgeon to Charing Cross Hospital, was elected a member of the Court of Examiners; Dr. G. F. Blacker, Obstetric Physician at University College Hospital, was elected an Examiner in Midwifery under the Conjoint Examining Board; Mr. R. J. Godlee was elected a representative of the College on the Senate of the University of London; and Mr. A. P. Gould was elected a member of the Committee of the Imperial Cancer Research Fund.

# A CLINICAL LECTURE ON VARICOCELE. (a)

By D'ARCY POWER, F.R.C.S.,

Surgeon to St. Bartholomew's Hospital.

GENTLEMEN,—I thought that to-day I would go over with you the question of varicocele. The operation for it always seems to be a simple one, and it is somewhat remarkable in that patients come to the surgeon and actually ask to have it done. Usually, of course, the surgeon has to exercise some degree of suasion to get the patient to consent to an operation. And I want you to refrain from thinking too little of the operation; it is not so trivial as it may appear, as you will presently see. As this man stands before you, notice that the left side of his scrotum is more pendulous than the right; and as he moves his penis to one side you see the whole of that side has an elongated full appearance. There are a few veins running over the surface, and within there is a whole plexus of veins, constituting the varicocele. If he were to lie down, that varicocele would disappear; if he coughs, there is a slight impulse, so that, if you were very careless, you might mistake it for a hernia. If, when he is lying down, you put your finger on the external ring and ask him to get up, you find the varicocele comes back, in spite of the pressure which you are exercising there. But a hernia could not come out through the external abdominal ring. The reason the varicocele comes back is, that you do not compress the spermatic artery, and therefore it still conveys its blood, and the veins fill up. And, secondly, when you press on the veins you prevent blood passing along. This patient, æt. 32, tells us he only noticed this trouble three years ago, when he was first told about it. From time to time he has had pain and dragging sensations; and his testicle has occasionally been swollen, without any definite cause. He now comes asking for something to be done for it. I may tell you, now that the patient has gone, that apparently he has had gonorrhœa, when he got some epididymitis, which was much worse on the left side, and no doubt it is chiefly that which brought him here.

The causes of varicocele, as far as we know, are the same as those producing varicose veins. People are born with weak veins, and that weakness, in the case of the testicle, is exaggerated, and the large pampiniform plexus being affected, the blood does not pass readily or easily through. Beyond that, there is no very definite cause assignable. The condition occurs usually between puberty and 35 or 40 years of age. You rarely see varicocele occurring in men over 40, when the generative functions begin to fall into abeyance; moreover, at and just after this age, varicoceles which have existed earlier tend to disappear. So in a man of 45 to 50 one would not advise operation for the condition, but palliative measures.

The symptoms are partly those which I have told you; there are also mental symptoms, with discomfort, congestion, and inflammation. The mental symptoms are out of proportion to the others; the patient worries about his condition, especially if he is neurotic. So it is common to find that these patients have had all kinds of treatment, and they

have often been to quacks, who prey upon their anxieties.

*Sequelæ.*—But really the dangers attending the condition are not very great. As in the case of varicose veins anywhere else, an accident may lead to rupture, that rupture causing hæmatoma; and if the patient does not lie up and rest, the hæmatoma may become infected, and lead to suppuration. Occasionally, instead of rupturing, the enlarged veins in a varicocele get inflamed or thrombosed. You may be sent for to a case of thrombosis occurring in connection with varicocele, which has come on spontaneously; and, unless you are careful in your examination and in your inquiries, you may jump to the conclusion that the patient has got a strangulated hernia. But you should not mistake a strangulated hernia for varicocele which has become thrombosed; and it only requires a little care to distinguish them. What most commonly happens is that, as the result of chronic congestion and imperfect blood supply, the testicle gets softened, and it may become smaller than its fellow. Mostly the condition is on the left side. The subject of the varicocele is probably frequently examining his testicle to see if it is softer than it was a little time back. If you assure him that it is usual to have softening or wasting of the testicle, but it is not serious in any way, you may comfort him mentally.

The treatment, which is what I want to specially draw your attention to to-day, is of much more importance. I have said that patients come asking that the operation may be done; the fact being that there are certain public services—Police, Naval and Military, etc.—in which candidates are debarred from entrance if they have varicocele of any considerable size. Such cases will come to you in private, as well as go to hospitals. If you are unwise you will consent and will undertake the operation lightly; you will do what you have been accustomed to see done. But no surgical operation is really trivial, and in that for varicocele there are many pitfalls for the unwary. One can impress that upon oneself in this way: When I was dresser here, in 1882, only one operation for varicocele was done in this hospital in that whole year. Surgeons had a rooted objection to operating on any vein. They had been told that people who had veins operated upon died. That was true in a large number of cases; they died of pyæmia. Some years after that no operations were done for varicocele at all, so I suppose that one case in 1882 must have died. About 1887 or 1888, when Listerian methods were more satisfactorily carried out, some twenty operations were done in a year in this hospital. And then followed a significant blank for two or three years. From 1897 onwards, the number of varicoceles operated upon has increased; it was 88 or 90 two years ago; and we had 55 last year. Mr. Pringle has looked out twelve of my own cases. That number would have lasted our older surgeons several years. Yet I am not quite satisfied with the operation for varicocele as it is done at the present time. We have tried a variety of methods, and, as the old method was purely palliative, we

(a) Delivered at St. Bartholomew's Hospital, on Wednesday, Oct. 27th, 1909.

need not trouble further about that. Wormald's ring was put over the scrotum and pressed tight above the testicle, and the weight of the column of blood was controlled in that way. Then came the disastrous time when underpinning through the scrotum was done, and a piece of silk was tied crosswise above and below. In one or two hands it acted very well, but others who tried it found suppuration occurring and very extensive orchitis. That method has also gone out of vogue.

Then there came the modern method, which was divided into two kinds of cases. The first procedure was to cut down through the scrotum—I will give you the details directly—to tie the pampiniform plexus, cut the ligatures short and close to the wound. This operation was done for a long time, and gave very satisfactory results: that is to say, when the results were favourable they were very satisfactory. But here again a considerable proportion of cases suppured; it was very difficult indeed to keep the scrotum clean, because you know it puckers up, and the dartos keeps the skin in such folds that it is difficult to get to the bottom of them. The methods which were adopted were, I think, somewhat favourable to suppuration. We were in the antiseptic period, and we washed the scrotum with strong antiseptics like carbolic or perchloride. The skin there is very delicate, and consequently, after the antiseptic had been on 24 hours, there was an eczematous condition of the skin, which was a favourable site for suppuration to commence at. There were many failures; the wound did not heal by first intention and the suppuration sometimes extended to the testicle, which sloughed. So we gave up that method.

We improved upon it, as we thought, and instead of cutting into the scrotum, we went higher up, by the external abdominal ring. We made an incision as if for the radical cure of hernia; and instead of tying the pampiniform plexus, we tied the spermatic veins, took out a little piece, and shortened the cord. But we had been too clever. I have been through the cases we have had, and a certain proportion of them have failed, because, although there was good union by first intention, so much of the veins was removed that the testicle suffered, and there has resulted an undue proportion of hydroceles, and a considerable amount of swelling of the testicle itself; so that people who came with varicoceles have been sent away with chronic orchitis, because there were no veins to carry back the blood from the testicle. For that reason, during the last two or three months I have gone back to the older plan of incising in the scrotum, and then I know it is very unlikely I shall take away the whole of the veins, because one cannot separate them completely; there are always enough left to allow of the passage of blood from the testicle. But we have avoided packing them or preparing them with the antiseptics which were used on previous occasions. Instead of using antiseptics, we thoroughly clean them up, and use either very dilute solutions, or salt solution. And nearly everything is used dry: we employ as little lotion as possible. And those cases have done excellently well, much better than the old high operations.

When you have to do the operation, just remember some details about it. First of all, you prepare the patient in such a way that no irritation of the skin is caused; you must bear in mind all the time that the skin here is very delicate, and you must not set up eczema or dermatitis by your preliminary treatment. I would rather the patient were washed on the operating-table with ether soap and biniodide lotion, and at once proceed to operate, rather than prepare the skin overnight, and pack him up, with

the subsequent risk of chafing. You want a good assistant, who should devote himself to nothing except keeping the vas deferens away from the vessels which you are going to tie. He has enough to do if he holds the scrotum up with the index fingers and thumbs of his two hands, and is sure he has got the pampiniform plexus just underneath the skin, and that the vas is below his fingers. He makes the skin quite tense, and when he has done that, you incise between the two fingers, *i.e.*,  $1\frac{1}{2}$  inches. Cut down through skin, and then through fascia, three or four or five layers, as the case may be, until you come down to the veins themselves. The mistake is to try to pass the needle under the pampiniform plexus before you come down to it. This plexus lies in several layers of fascia, and you must divide each if you are going to get the best results; go right down until the veins shine out as black things; and even then there is another layer of fascia which you can divide. So the essence of the operation is freeing and seeing the pampiniform plexus. And do not let your assistant move his fingers, otherwise the vas deferens will slip up, and you will almost certainly tie the vas with the veins. Remember that the veins lie packed together in little packets. Take an aneurysm needle, pass it beneath the packet of veins which you have freed. It is a proof that you have freed them sufficiently if you have to use no force to pass your aneurysm needle. If the needle will not pass freely underneath the veins, or if you have to cut down upon the end of it you have not divided all your fascia. Better it is to take your needle out again, take up your scalpel and forceps again, and go on cutting through the fascia until you can pass your needle readily, than to force the aneurysm needle through tough fascia. When you pass your needle under the veins, you should be able to move it to-and-fro at least an inch, so that there is an inch of that plexus exposed in the wound. Pass a double ligature through the eye of the needle, withdraw your needle—and your ligature will be of catgut for choice; then tie the pampiniform plexus in two places, where you have freed it, that is to say, an inch apart. The parts are many, and you must get your knot tied into the veins, slowly, evenly and securely. When you have the ligatures tied, put a pair of pressure forceps above and below each. It happens to even the best of us that when we think we have securely tied a ligature, it slips off; therefore you must have your pressure forceps to pull upon the ends if this accident should happen. Cut out a piece of the veins between the two ligatures, generally about half an inch. You want to leave a fair piece of vein between the end of the ligature and the point where you divide; otherwise the ligature will certainly come off, and if it does, it is a disaster, as far as that particular case is concerned. There is certain to be much bleeding from the ends of the veins. A good varicocele operation is bloodless from beginning to end, and that is a very important factor in the subsequent repair. If you are at all careless or rough you are certain to have a hæmatoma. You have two ends of divided veins, and the first thing which strikes you when you divide them is: "I have certainly got that vas after all." But it is not. When you look at the veins they are so thickened, and the walls are so thick that unless you cut sections and microscope them, you cannot tell the vas from veins. These thickened veins nearly always stand out. Take the two ends of the catgut ligature, and tie them together, so that you bring the ends of the veins into apposition. There must be a lump; you cannot help it. It is of no use trying to get them into exact apposition. Then bring the skin edges of the wound

together; you need not trouble about the fasciæ, and be very careful that the skin edges are not turned in. The proper way to get them into apposition is for your assistant to let go the scrotum which he has been holding all this time, put a blunt hook on either side, and pull the ends tight. Then you can easily sew the edges. It is better not to use a continuous suture, use three or four interrupted sutures of fine catgut. If you get everything quite dry the subsequent dressing should be colloidion and wool. In about seven or eight days' time the patient can go out; there is no reason to keep him in bed after taking the stitches out.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The Lecture for next week will be by Walter C. Stevenson, M.D., B.Ch., Surgeon to the Orthopædic Hospital of Ireland, Dublin. Subject: "The Treatment of Congenital Talipes Equino-Varus in Infants."

## ORIGINAL PAPERS.

### CONCERNING TRACHOMA. (a)

BY ARTHUR H. BENSON, F.R.C.S.I.,  
Surgeon to the Royal Victoria Eye and Ear Hospital, Dublin.

GENTLEMEN,—My first duty is to thank you for the honour you have done me in electing me President of this Section, and I do so with all sincerity.

My next duty is to thank Professor White, on behalf of the Section, for his long and faithful services as Secretary, and to greet his successor, Dr. Boxwell.

It is a very usual thing, in opening a new session, for the President to review the work done during the previous session; but in the present case such a recapitulation would seem to me to be profitless.

I prefer, rather, to call your attention to one subject of the first importance to all humanity, and to the inhabitants of this country in particular, in the hope that by your efforts a serious blank in our knowledge may be filled.

Trachoma, or granular ophthalmia, is one of the greatest curses that weigh down and oppress the poor in this distressful country.

It is the plague of all our workhouses, industrial schools, and eye hospitals.

It is the "opprobrium ophthalmicum"; for though, like the poor, whom it principally attacks, it is always with us, yet we have no certain knowledge as to its true nature or its ultimate cause.

I trust that some of those members of the Section who have energy, and enterprise, and time, and opportunity, will undertake original investigations into the essential cause of the condition which, year by year, is responsible for the blinding of thousands and the partial incapacitating of tens of thousands of our fellow-countrymen.

Whoever discovers the actual essential cause of trachoma will thereby erect for himself a monument more lasting than brass, and will have earned the gratitude, not only of a nation, but of the whole world.

Much has already been done to prepare the way.

A few years ago every form of conjunctivitis was described and catalogued solely in accordance with its clinical appearances and characteristics.

Now most of them are identified bacteriologically, and their specific cause is known with certainty.

Acute catarrhal conjunctivitis is known to be caused by the slender bacillus of Koch and Weeks.

The Morax-Axenfeld diplo-bacillus produces a characteristic form of blepharo-conjunctivitis.

The pneumococcus produces a less characteristic form of conjunctivitis, with pinkish œdema of lid margins, and often rapid subsidence of the symptoms, reminding one of the "crisis" in acute pneumonia.

Löffler's diphtheria bacillus produces its characteristic membranous conjunctivitis.

The gonococcus is responsible for gonorrhœal

ophthalmia, and many cases of ophthalmia neonatorum.

The streptococcus, bacterium coli, and tubercle bacillus each produces forms of conjunctivitis that are definite clinical entities, and as the cause is recognisable, so the line of treatment emerges from the twilight of empiricism into the full day of scientific certainty.

But trachoma, which draws its victims from all periods of life, and with bulldog tenacity holds them in its grip, as yet owns to no specific cause, yields to no specific toxin.

We still treat it much as it was treated fifty years ago (or, for the matter of that, two thousand years ago), and with a most humiliating want of success.

All the evidence points to its being micro-organic in origin, but the special causative germ, this "scarlet pimperl" of bacteriology, still eludes the vigilant search of microscopes in every land.

Every few years our hopes are raised by the publication of a full description of the "notorious criminal," with portraits of his development, from youth to age, but, so far, in every case he has been able to prove an alibi, and has left the Court without a stain upon his character.

Just at present the trial of the most recent "suspect" is in full swing. Through the kindness of Dr. Mooney, I am enabled to show you not only his portrait, but the individual himself under one of the microscopes. The so-called "Trachoma corpuscle" (a) of Greeff. Professor Greeff sent him to Sir Henry Swanzy, who lent him to Dr. Mooney, who brought him here to-night.

Later on we shall have more to say on the subject.

Trachoma is known in practically all countries, it is a scourge in many, and its presence has been recognised from the remotest ages, but it was the devastating epidemics of the latter years of the 18th century, and the beginning of the 19th, that first riveted upon it the attention of the medical profession in Europe.

In 1798 Napoleon landed an army of 32,000 men in Egypt. A very large number of these were attacked by a violent inflammation of the conjunctiva, to which the name "Egyptian ophthalmia" was applied. On their return to Europe they brought the disease with them, and in the period of the Napoleonic wars, when all the armies of Europe were repeatedly in contact, the disease spread with such appalling rapidity that a few years later we find it epidemic in every army in Europe. In the English army, during the year 1818, there were more than 5,000 men on the invalid list, blind from trachoma. In the Prussian army, from 1813 to 1817, over 20,000 men were attacked with this disease. In the Russian army, from 1816 to 1830, 76,811 men were suffering from trachoma. In Belgium, in 1840, one out of every five soldiers was afflicted with trachoma.

These soldiers, invalided home, carried the disease to their families, and spread it through every quarter of their country. Hence trachoma became epidemic in almost every state of Europe. At this stage it became usual to describe it as "military ophthalmia."

Among the civil population trachoma finds a soil suitable for its development wherever many persons are crowded together with imperfect hygienic surroundings. Hence, when in 1841 workhouses became established in Ireland, they formed excellent culture beds and disseminating depôts for the disease, and, in spite of the improved hygienic arrangements, trachoma still flourishes in every union workhouse throughout the land.

It is a remarkable thing that whereas trachoma is a national calamity in Ireland, it is an extremely rare disease in England, and would most assuredly become extinct there but for the influx of infected aliens.

England, as has been said, is a trachoma filter-bed for the United States, and Ireland suffers in the same manner, but the better hygienic conditions prevailing in England have saved it from our fate.

Trachoma is a disease venerable by its antiquity. It is believed to be the disease alluded to in the oldest book on medicine that is known, the Ebers Papyrus.

(a) Presidential Address delivered at the Opening Meeting of the Pathological Section of the Royal Academy of Medicine in Ireland, Nov. 12th, 1909.

(a) Provazek calls them "Clamydozoa" (mantellene, i.e., organisms with mantles). Many writers call them "Provazek bodies."

written in Egypt about 3,400 years ago—i.e., about a thousand years before Hippocrates. Celsus describes the disease, not by name, but in indisputable language. It was well-known among both the ancient Greeks and Romans, as Boldt mentions in his exhaustive work on "Trachoma" (from which, as also from Fuchs and Axenfeld, I have borrowed freely).

It is alluded to in the comedies of Aristophanes, and in a certain Greek play those desirous of avoiding service as marines are represented as pleading ophthalmia as an excuse.

How modern these old Greeks were!

It is stated that Meshullam ben Menachem, in 1481, and Obaja, in 1488, are the first to mention that eye disease was then, as it is still, almost universal in Egypt; but how long before this the disease had become pandemic it is difficult to say.

Trachoma, with us, shows itself under two rather different aspects—

(1) *Papillary trachoma*, characterised by an increase in size of the surface of the hypertrophic conjunctiva, so that it is thrown into folds with deep clefts between: the connective tissue forming the papilla is stuffed full of round cells; and

(2) *Follicular trachoma*, characterised by the presence of the true trachoma bodies, which are rounded accumulations of cells, between which a very delicate connective tissue framework can be made out. The cells in the marginal portions of the granulations are lymphocytes; in its anterior parts are predominantly uninuclear leucocytes (epithelioid cells), between which lie a few particularly large cells (phagocytes), which contain in their protoplasm small, deeply-staining corpuscles (Fuchs).

There are certain points that may be worth bearing in mind by anyone about to undertake an investigation into the cause, the intimate specific cause, of trachoma.

Amongst the lower animals monkeys are said to be the only ones affected with trachoma.

The conjunctiva and lachrymal sac are the only mucous surfaces affected with the trachomatous type of inflammation.

Trachoma cases are nearly always complicated by the presence of some one or more of the well-known pathogenic organisms, which must be regarded as a complication, and not the cause of the condition, a mixed infection being almost the rule, the most important complicating organisms being the Koch-Weeks bacillus and the gonococcus.

The history of the earlier epidemics, and the frequent presence of the gonococcus, has led some to hold that trachoma arose originally from the action of the gonococcus. Indeed, so lately as 1905, Bishop Harman writes:—

"The conclusion I am driven to, after examining all the evidence at my disposal, is that, so far as microbic influences can be determined, the trachoma of our time is probably the result of an inoculation of the conjunctiva with the micrococcus gonorrhœa of an attenuated virulence, the effects of the inoculation being so mild that they are not noticed; consequently, in England we never obtain definite evidence of the organism, the case being seen too late."

Trachoma is essentially a chronic disease. Acute trachoma is a disease which begins acutely with profuse secretion, and in the majority of cases is not a pure trachoma, but a mixed infection with an acute catarrh.

Perhaps the most perplexing fact in connection with the subject of the contagiousness of trachoma is the unilaterality which is now and then observed.

I have several times found a typical trachoma of several years' standing in one eye, whilst in the other eye of the same individual no trace of disease, past or present, could be seen.

No satisfactory theory has, so far, been put forward to explain this anomaly.

It is impossible to suppose that direct local infection had not taken place during those years, and such explanations as "local immunity" are mere words, and do not help us.

The infectiveness of trachoma is greatly increased during the acute exacerbations caused by the presence of other organisms, such as the Koch-Weeks bacillus

and the gonococcus, the diplo-bacillus of Morax-Axenfeld, or the pneumococcus.

Simple chronic granular ophthalmia possesses but a low degree of infectiveness, but predisposes the conjunctiva to the attacks of other micro-organisms, whose activities at once raise the infectiveness of the trachoma virus.

Drying of the conjunctival secretion seems entirely to destroy the infectiveness of the trachoma virus.

No life period is proof against trachoma.

Acquired immunity cannot be demonstrated.

The influence of personal disposition cannot be denied.

The influence of race predisposition is doubtful.

The influence of environment is all important.

Trachoma has never been produced by inoculation with pure cultures of any known micro-organism, though it has, from time to time, been stated to be caused by—

(1) The gonococcus, as mentioned before

(2) The Koch-Weeks bacillus (Gromakowski).

(3) Micro-organisms, designated "trachoma cocci," have been found by Michel, Sattler, and many others, but Axenfeld says they are not constant, and are not the cause of the condition.

(4) Bacillus Xerosis (Shongolowicz).

(5) "Microsporon trachomatousum," a fungus which Noiczewski thought he found.

(6) Ultra-microscopical bodies are described by Raehlmann and Santucci, but their causative power requires proof.

(7) L. Muller has found a small bacillus—like the influenza bacillus, but it is not constant, and is not the cause of trachoma.

Everything is in favour of trachoma being a specific infectious disease, the cause of which is not yet definitely determined; but, as I mentioned before, there is now another prisoner in the dock—the organism discovered almost simultaneously by Professor Greeff in Germany, and by Halberstädter and Prowazek in Java, and verified by Mijaschita in Japan, and by others in different countries.

At the Ophthalmological Congress, in Oxford, in July last, and subsequently in Belfast, Professor Greeff demonstrated the organism which he regards as the cause of trachoma. He says:—"The bodies I found were very regular, round, cellular inclusions, which were much smaller than the smallest known coccus. They stain intensively, sometimes violet, sometimes reddish or blue, with Giemsa diluted with aniline stains, and not at all with Gram. They are surrounded by a distinct, clear zone. With the strongest powers of the microscope, one observes that they are not quite round, but a little oval, like bacteria with rounded extremities. Finally, they are isolated, or grouped in pairs or in masses. If intracellular they lie close to the nucleus. We found the formations in the epithelial cells, in the discharge, in the pressed-out follicles, and, indeed, everywhere they were looked for."

The bodies can also be seen in sections "in the sub-epithelial tissue, in the lymph spaces beneath it, in the cells of the follicles (the lymphoid and the so-called Leber's cells), and between the cells."

Greeff states that these bodies are a constant characteristic of trachoma, as he has found them in every recent case of trachoma (not under treatment), and, further, that he failed to find them in any other form of conjunctivitis.

Caustic applied to the conjunctiva makes them vanish for the time, but they recur. These bodies invade the cell, increase in number, and congregate in a mass close to the nucleus, multiply till they fill the cell, and finally burst free into the tissues.

"It would as yet," he says, "be premature to attempt to assign to the trachoma bodies their place in the zoological system. They are certainly not bacteria; on the contrary, they are more closely allied to the protozoa." (a)

In these disjointed remarks I have brought forward nothing original, I have stated nothing new. My object has been to attempt very briefly to recapitulate some

(a) A cell with a mass of these in it was on view under the microscope.

of the results of the last twenty years' work on this subject, in the hope that it may serve to stimulate some of the younger men here to undertake the task of verification, and by original work to throw light upon these dark places.

Are these organisms really the cause of trachoma? That is the great question of the hour. It may be easy to demonstrate their specific nature, but their parasitic and causative nature is quite another question.

We have so often been disappointed in the past that it behoves us to accept with caution all statements, and test for ourselves the facts. At present our only verdict can be, "Not proven."

I know the subject is difficult, but if it were not difficult neither would it be interesting. I know that it is not easy to get the time and the energy to carry on any extra work for, as the great Samuel Johnson said, "What we think of importance we wish to do well; to do anything well requires time, and what requires time commonly finds us too idle or too busy to undertake it."

Through the labours of your predecessors, as I have tried to show, many solid facts have been established; much of the mist and obscurity that surrounded the subject has been cleared away.

But there is plenty of original work still to be done, for, even supposing that the organism under the microscope there is the long-sought microbe, that is only the first step.

Its life history has to be worked out, its origin and its metamorphoses have to be investigated, and its likes and dislikes observed. Not till these have been done can any advantage be obtained from the primary discovery.

The material for such investigations is at your hand. I can give anyone who wants to work as many cases of trachoma as he wishes. Our eye hospitals are full of them, our workhouses are full of them, our blind asylums are full of them, the whole country is full of them—there is no lack of material. Much has been done, but much remains to be done, and this is the place to do it.

In conclusion, I will tell you a story.

Two mice in a pantry were foraging for food. One of them slipped into a jug of cream, and was like to drown. "Keep kicking," cried his friend on the shelf. "But I can't swim," said the one in the jug. "Never mind," said his friend on the shelf, "keep kicking, keep kicking." "What good will that do?" said the half-drowned one in the jug. "Never mind, keep kicking."

In the morning, when the pantry was opened, Mr. Mouse in the jug was found sitting comfortably up on a pat of butter!

My advice to you is "Keep kicking."

## ABDOMINAL HYSTERECTOMY SIXTY-THREE HOURS AFTER LABOUR FOR A NECROSED AND SUPPURATING SUB-PERITONEAL FIBROID. (a)

By PHILIP D. TURNER, M.D.,

Hon. Medical Officer to the Royal Isle of Wight County Hospital;  
Medical Officer of Health for the Borough of Ryde.

Mrs. S., æt. 32. Married 13 months, nullipara, consulted me March 22nd, 1909, on account of a hard lump which she had noticed in the left side of her abdomen for about a fortnight. Her last menstrual period ended on January 18th, and the ordinary symptoms of pregnancy were present.

I found a firm, elongated, freely movable tumour lying on the left side of, and attached to, the uterus, which was about two months pregnant. I considered it to be a pedunculated fibroid, and took her into hospital with the intention of removing it.

On April 8th I opened the abdomen, and found that the fibroid was attached to the uterus by a

very broad base; and I did not consider that it could be removed without terminating the pregnancy, or without considerable risk. As its position on the left angle of the fundus was not likely to allow it to interfere with the course of pregnancy or labour, I decided to let the case go on to term, and perform a myomectomy later on.

Till about the seventh month the pregnancy was normal; but from that time she had pain in the region of the fibroid after any exercise.

Labour commenced on October 26th, but full dilatation was only reached at 9 p.m. on the 29th. Throughout the labour the pain was most severe over the fibroid, which felt harder and tenser than when I had examined it a fortnight before.

The second stage was short and, towards the end, precipitate.

The child—a boy—was born at 11.45 with a very long cord three times round its neck. There was rather sharp post-partum hæmorrhage, and, introducing my hand, I found placenta and membranes adherent, and had to strip them off. In doing so I felt a very small intramural fibroid in the anterior wall, and a somewhat larger sub-mucous one near the right cornu.

The pulse after labour was 86.

On the 31st, in the morning, the pulse was 98, and the temperature 100.2. The tumour was tender and painful. The lochia was scanty and sero-sanguineous.

In the evening she did not feel so well. Temperature 100.4; pulse 106. I ordered a dose of castor oil.

On the morning of November 1st (third day) the bowels had been well opened, but the patient was looking ill and anxious. The region of the tumour was very tender, and the pain in it had kept her awake the greater part of the night. The whole abdomen was somewhat tender, the temperature 100.2, pulse 126.

The lochia were almost absent, represented by a little clear serum only. There was a rather extensive superficial slough on the lower part of the vaginal wall on the left side; this I swabbed with pure carbolic acid.

In view of the steady and progressive rise in the pulse rate, combined with the increasing pain and tenderness over the tumour, I concluded that the fibroid was sloughing, and advised the relations that the patient's only hope of recovery, and that a very slender one, lay in immediate operation.

I operated at 3.15 p.m., 63 hours after the birth of the child, and I removed the uterus by Doyen's method. Some delay and rather free hæmorrhage occurred during the division of the vagina.

Three or four pints of saline solution were introduced into the abdomen, while the wound was being closed. This caused the pulse, which had become imperceptible, to revive, and at the end of the operation, which lasted nearly three-quarters of an hour, it was not much worse than when I began.

An hour later three pints of saline were introduced into the median basilic vein, with one drachm of adrenalin—1 in 1,000 to each pint.

The convalescence was without incident. The pulse for five days did not fall below 120, and was at times as frequent as 140.

The left edge of the abdominal wound sloughed a little owing to interference with its blood supply by the scar of the former operation.

*Description of parts removed.*—The specimen consists of the puerperal uterus with a tumour about the size of the head of a three months' baby, slightly ovoid in shape, which has grown from the left angle of the uterus in front of the broad ligament.

(a) Paper read before the Obstetrical and Gynecological Section of the Royal Society of Medicine, Dec. 9th, 1909.

The round ligament comes over the back of the base of the tumour.

On slitting up the uterus, its cavity is found to run up into a pocket two inches deep on the inner side and to the back of the tumour. There is a small submucous fibroid, the size of a shelled walnut, near the right cornu on the anterior wall. A second, still smaller interstitial fibroid, is situated about the middle of the anterior wall.

The lining membrane is shreddy; but not unhealthy looking. The placental site is on the anterior surface extending to the fundus; but not including the pocket.

On incising the tumour there was a gush of excessively foul and stinking pus. The tumour is almost entirely converted into an irregular cavity lined and trabeculated by yellowish grey opaque slough. This is bounded by a layer of apparently normal fibroid, which on the side nearest to the uterus is three-quarters of an inch thick, while at one point of the incision it is less than one-tenth of an inch, so that the slough is covered by very little more than the peritoneum.

*Remarks.*—This case seems to me one of considerable interest, as an example of one of the accidents which may befall an apparently harmless specimen of fibroid tumour during pregnancy.

I have no doubt whatever that when I opened the abdomen in the third month of pregnancy the fibroid was in a normal condition. On the other hand a mere glance at the condition of the specimen is sufficient to satisfy anyone that the necrotic change must have gone on a considerable time before labour.

The patient began to feel pain in the tumour on exertion about the seventh month of pregnancy; and I imagine that the central necrosis of the fibroid took place about that time, or shortly before.

It is interesting, too, that there should have been no symptoms suggesting any absorption of poison from the tumour till after labour.

A further point of interest lies in the ætiology of the changes in the tumour, which, as I have found so little allusion in the literature to necrosis and suppuration of subperitoneal fibroids, I assume to be a rather rare event. Pregnancy in conjunction with such tumours is comparatively frequent, and does not usually have any untoward effect upon their nutrition. Similar changes in submucous fibroids are usually ascribed to infection; and I should like to hear the opinion of Fellows whose experience is larger than my own, whether the necrosis could have been in any way brought about by the first laparotomy.

The operation was a simple exploratory one. The tumour was examined *in situ* and not brought outside the abdomen. It was exposed to no unnecessary handling. There was no rise of temperature after operation, and the wound healed absolutely by first intention.

Can it be that the ordinary handling of the tumour may so far have damaged the peritoneal surface as to allow infection to occur from the neighbouring bowels? If this were the case the complete absence of any symptoms for four months after infection seems extraordinary.

With regard to the treatment pursued, the only alternative would have been to do a myomectomy or hysterectomy at the first operation. The former would certainly have terminated the pregnancy; and, considering the usually normal course of pregnancy, labour and puerperium in such cases would, I think, have constituted the more serious danger. A fortiori I believe that hysterectomy would have been entirely unjustifiable.

After labour the symptoms did not leave any alternative.

## NOTE ON A CASE OF CYSTIC TUMOUR OF THE RIGHT BROAD LIGAMENT SPRINGING FROM THE UTERUS, AND APPA- RENTLY DEVELOPED FROM GARTNER'S DUCT. (a)

By ARTHUR H. N. LEWERS, M.D.,

Senior Obstetric Physician to the London Hospital.

H. M., a primipara, æt. 47, was admitted into the London Hospital under my care on March 24th, 1909.

*Present illness.*—On admission she complained that for the last month there had been frequency of micturition during the day, and that she had been unable to empty the bladder properly in the morning. For about the same time she had also noticed a swelling in the lower abdomen, and had pain and flatulent distension after meals.

*Physical signs.*—On examining the abdomen a fluctuating tumour was felt rising from the pelvis to a height of one inch above the umbilicus. It was fairly central in position.

On vaginal examination the vaginal position of the cervix could only be reached with difficulty. It lay high up, and to the left. A tense swelling, which seemed to be continuous with the tumour in the abdomen, was felt bulging down the vaginal roof and right lateral fornix.

### OPERATION.

*Operation, March 26th, 1909.*—The abdomen was opened in the usual way, and the cyst, covered by the anterior layer of the right broad ligament, came into view. It was punctured, and about two pints of thick, chocolate-coloured, odourless fluid escaped. The relations of the cyst were carefully examined. The partially collapsed cyst was found to lie in the right broad ligament. It partly overlapped the anterior surface of the uterus, extending in that direction nearly to the middle line. The right tube and ovary were normal, and lay behind the cyst, the posterior peritoneal layer of the broad ligament intervening. The bladder was drawn up, and lay in close relation to part of the anterior surface of the cyst.

In order to facilitate enucleation the collapsed cyst was tightly packed with gauze so as to define its exact limits.

Enucleation was easy in every direction till the right side of the uterus about the level of the internal os was reached.

Here the cyst was firmly attached to the uterus by a pedicle of uterine tissue, about an inch in diameter. This was divided with scissors, and during the process several small loculi the size of a pea were opened. The contents of these looked like thick yellow pus; closer examination showed the material to be inspissated mucus, the cavities in question being lined by a secreting surface. Several large vessels were cut across when dividing the pedicle, and these had to be controlled by under-sewing with silk ligatures. The deeper part of the cyst extended much more deeply downwards than is the case with ordinary broad ligament cysts, and it was in close relation with the vaginal wall on the right side, below the level of the vaginal portion of the cervix, for a distance of at least an inch. Nothing was seen of the right ureter during the enucleation, though it was, of course, looked for. After all the bleeding points had been secured, the edges of the right broad ligament were brought together with sutures, but not so as to make the

(a) Paper read at a meeting of the Obstetrical and Gynecological Section of the Royal Society of Medicine, Dec. 9th, 1909.

cavity, from which the cyst had been removed, watertight.

The left uterine appendages showed signs of chronic inflammation, and were removed. The uterus was retroverted, but was otherwise normal. The patient made an uninterrupted recovery.

The removed cyst, collapsed and shrunken after immersion in 5 per cent. formalin, measures 6 by 4 inches, but in the recent state was the size of an adult head.

On the outer surface of the cyst are seen two smooth bosses, the size of marbles. There are two small cystic cavities not communicating with the main cyst; one of them has been laid open, and a section taken through its wall. The other remains intact.

The microscopic examination supports the view that the tumour represents a collection of dilated ducts and cysts in the uterine wall, probably arising from the intra-uterine portion of the Gartnerian duct.

### ON SOME RECENT ADVANCES IN BACTERIOLOGY. (a)

By CARSTAIRS C. DOUGLAS, M.D., D.Sc.,  
C.M. EDIN.,

Lecturer on Public Health, Anderson's College Medical School,  
Glasgow.

DR. DOUGLAS commenced his lecture by giving a *résumé* of the different dates at which the various known organisms of disease were discovered, and that very great strides had been made in the discovery of these organisms in the last twenty years, and which could not advance at the same ratio in the present decade. About 90 per cent. of the effects of specific disease are due not to the organisms but to their toxins, and if long enough time be given, we find that Nature produces the antidote to these organisms and their toxins. We do not attack the symptoms of these diseases, but endeavour, by the aid of rest, nourishing diet, fresh air, attention to the skin, etc., to uphold the strength of the patient and so tide our patient over the dangerous period of the disease.

In speaking of the *habitat* of various organisms Dr. Douglas took as his type the pneumococcus and stated that 20 years ago it was regarded as essentially in croupous or lobar pneumonia, and it was believed, for a long time, that the pneumococcus found a home only in the pulmonary alveoli, but since then it has been found to have a wider extension, such as the bronchial and nasal secretion, and it may attack any tissue or organ and produce such diseases as pleurisy, endocarditis, otitis media, etc., and Parke and Williams, of New York, in 80 patients found the pneumococcus present in the bronchi of 40 of these who were apparently healthy individuals. Dr. Douglas stated that the pneumococcus is practically always in the blood in pneumonia, and in a fair number of cases it is possible to get clumping, just as in typhoid, but it is not so marked as typhoid, and usually occurs about the crisis. The chief organisms against which the clumping or agglutinating test may be, with a reasonable amount of success, attempted, are Malta fever, which is now a somewhat rare disease, typhoid, bacilli coli, diphtheria, human glanders, pneumonia, dysentery, ptomaines, specially if Gartner's bacillus, and whooping-cough.

The lecturer stated that the bacillus typhosis occurs very early in the blood, in 90 per cent. of cases within the first week, and related several cases of chronic typhoid carriers disseminating the disease years after their own recovery, and laid

particular stress on the point that they were not constant carriers but only intermittent. With regard to water Dr. Douglas states that when water has become affected with the typhoid bacilli that it entirely disappears from this same water in 5-7 days, and that the bacillus lives longer in sterilised or Pasteurised milk than it lives in ordinary milk. He maintained that it is the moist spray which is ejected from the mouth of a tubercular subject, that is the source of infection, and not to such a great extent by the sputum which has become dry and floats about. This he proved by keeping a guinea pig within the sneezing zone of the patient, but not in contact with him, and which afterwards developed tuberculosis. The lecturer also believes that tubercle is a disease which is ingested rather than swallowed, as accumulated evidence shows that the tubercular bacilli can find its way through the undamaged epithelium of the intestine, and the mesenteric glands of the child are far more frequently attacked than the bronchial glands. The lactic acid (sourine) treatment of tuberculosis is still *sub judice*.

Dr. Douglas discussed the Wasserman reaction for syphilis, and explained that it entailed the fixation of the complement and was based on Ehrlich's side chain theory. To illustrate what really happened Dr. Douglas made use of an ingenious model, on which he was able to demonstrate the part played by the spirochæta (or other organisms), side chains, immune body, and complement respectively, and which appealed far more to the practitioner than any amount of theory or book knowledge. Having described in detail how to perform the whole reaction the lecturer concluded by stating that it is not strictly accurate as the ordinary liver cell has given the reaction, and that the general practitioner requires something easier and less expensive.

### SOME PROBLEMS RELATING TO THE EVOLUTION OF THE BRAIN. (a)

By DR. G. ELLIOT SMITH, F.R.S.,

Professor of Anatomy at Manchester University.

THE lecturer first dealt with the historical development of the foundations of our modern knowledge of that particular part of the brain, the activities of which are concerned with mental phenomena. He pointed out the appropriateness of the Royal College of Surgeons as the place for discussing this subject, seeing that all our recent accurate knowledge of this part of the brain is based upon the work which has been carried on in the College museum during the last seventy years by its officers and by students, who drew their inspiration either directly or indirectly from the work done there. He described the early work of Sir Richard Owen on the brain of marsupials in 1836, and the eclipse of Owen's work in the disputes which followed on the publication of Charles Darwin's "Origin of Species," when the feeling of animosity against Owen by Darwin's champions was raised to such a pitch that the latter failed to discriminate between the good and bad in Owen's work. But the overthrow of Owen's excellent work on the marsupial brain was only temporary. After being discredited for a quarter of a century, it has been confirmed by recent research with modern methods, and has become the foundation of our present knowledge of the morphology of the brain in the vertebrata.

The lecturer described the chief stages in the evolution of the cerebral cortex, with the object of explaining the origin of the "neopallium"—the

(a) Abstract of Lecture delivered before the Glasgow Northern Medical Society, Dec. 7th, 1909.

(a) Abstract of a series of three Arris and Gale Lectures delivered at the Royal College of Surgeons of England last week.

name given by him to that part of the brain which, far more than any other, is responsible for the occurrence of mental phenomena. It is a part of the nervous system where sensory impressions of all kinds, tactile, visual, acoustic, olfactory, gustatory, &c., may meet and blend and arouse the memories of former sensations; thus it is the organ in which are born the consciousness of things present, the memories of things past; and all the higher psychical phenomena which result from the exercise of an associative memory. This organ only becomes developed in any definite form in the mammalia, although feeble attempts at the formation of an analogous structure are discernible in reptiles, and more distinctly in birds, whose brains, like their psychical potentialities, develop along highly-specialised and peculiar lines.

Professor Smith is of opinion that the neopallium probably originates in the immediate ancestors of the mammalia, when the skin over the whole surface of the body becomes transformed into a highly-developed tactile organ. Even in reptiles, and to a much greater degree in birds, impressions of touch coming from the tongue and the skin around the mouth make their way into the cerebral cortex. In these creatures also the cerebrum concerns itself with the consciousness of sight. But in the mammal sensory paths pour into this part of the brain in infinitely larger numbers, not only from these two or three special sense-organs, but from every sensitive surface in the body, and especially from the organs of touch scattered throughout the extensive area of the skin. Thus the cerebral cortex, which in the lower vertebrates was little more than a receiving instrument for impressions of smell, and perhaps taste, becomes in the mammal a place where every kind of sensation can blend, and not only awaken a consciousness of all the various properties of an object, as they appeal to the senses of smell, taste, sight, hearing and touch, but also an organ where such states of consciousness can leave impressions to be stored up and used for the purpose of interpreting present sensations in the light of past experience. The neopallium is the part of the cortex which subserves this function of associative memory, which lies at the root of all mental phenomena.

In the lowlier vertebrates, Professor Smith thinks that the nervous system may be likened to a confederation of more or less autonomous States; the cerebrum belongs mainly to the sensé of mell, and, perhaps, taste also, and, while contributing its quota to the control of the commonwealth, it is itself influenced only slightly by the other sensory mechanisms. The part of the nervous system which receives impressions of sight is the mid-brain, and in the lowliest vertebrata this plays a far more important rôle than the cerebrum. Other senses are represented in other parts of the brain, none of which, however, can be said to exercise a dominating influence over the rest, such as the cerebrum has in mammals. A lowly vertebrate, such, for example, as a fish, may see an object and recognise it as being desirable or undesirable; but the state of consciousness thus aroused is not greatly influenced by information obtained by other senses, such, for example, as smell and touch. Thus a fish readily mistakes an imitation fly for the real insect, and may not recognise food which is just as nutritious and appropriate as the fly, simply because it does not look like a fly. A frog or lizard may be disturbed by the sound of the gentlest splashing of water or rustling of a leaf, and yet remain undisturbed by the loudest noises made in close proximity to them. The organs of special sense in animals without a neopallium respond only to appropriate stimuli—only to those impressions which in the

course of evolution have come to possess some precise meaning for them. "As Professor Edinger has well said," remarked the lecturer, "a loud noise conveys no more definite sense of danger to a lizard than a warning notice on the edge of a precipice written in Chinese would have to the European." The neopallium, in other words, is a mechanism which enables its possessor not only to appreciate all the properties of any given object; it does far more than that; it enables him to correlate, to test and to judge present impressions with memories of past sensations and past states of consciousness which have been "stored up" in the great treasure-house of memories—the neopallium. The neopallium is first definitely recognisable as such in mammals, and at its first appearance it can already be mapped out into a series of areas, each of which is being cultivated by some particular sense. We have a storehouse for impressions of sight, another of taste, another for touch, and so on.

The further evolution of the cerebral cortex is brought about by the development between these sensory areas of new regions in which the impressions of the various senses meet and form the basis for still higher psychical activities than those of mere associative memory.

## OPERATING THEATRES

### ROYAL FREE HOSPITAL.

OPERATION FOR EPITHELIOMA OF THE TONGUE.—Mr. LEGG operated on a man, æt. 63, who six months previously noticed a small pimple on the posterior part of the right side of the tongue. For the last two months he had had occasional pain shooting towards the right ear. Six weeks ago the patient first noticed a lump on the right side of the upper part of the neck just behind the angle of the jaw. On examination a small ulcer was found just where the anterior pillar of the fauces and the dorsum of the tongue adjoin. The ulcer extended a short way above the former structure, and it had a hard, irregular edge. In the tongue, extending forwards to about its middle on the right side, a hard mass was found, and the movements of the tongue were somewhat limited. The lymphatic glands beneath the upper part of the right sterno-mastoid were enlarged, hard, and somewhat fixed, though not completely immovable. The lower limit of this mass was on a level with the hyoid bone; no other enlarged glands could be detected. In all other respects the patient was a well-preserved and healthy man for his years.

At the operation the glands were first removed through an incision extending from just above the angle of the jaw nearly as low down as the clavicle. From the middle of this incision a second curved one was made across the neck to the middle line, and the two flaps of skin and platysma so marked out were turned upwards and downwards respectively. All the fascia covering the muscles, and all the fat and connective tissue in the anterior triangle were removed, together with the submaxillary salivary glands. The jugular vein was exposed at the lower part of the neck, and tied in two places, then divided between two ligatures. Then a portion of the sterno-mastoid and all the fat and connective tissue beneath it in the upper part of the posterior triangle of the neck was dissected upwards and forwards. The glands were detached from the parotid by dissecting upwards to the base of the skull. The upper end of the jugular vein was isolated, tied, and divided between two ligatures. The mass of glands was then separated from the deep muscles and removed in one mass together with the jugular vein, the fat, and the fascia of the two triangles. It was necessary to remove also the posterior belly of the digastric and a portion of the spinal accessory nerve, as the glands were inti-

mately adherent to these structures. The lingual artery was next exposed at its origin from the external carotid and ligated about half-an-inch from the latter vessel. The lower part of the incision along the anterior border of the sterno-mastoid was now stitched together, and the remainder of the wound covered with sterilised gauze wrung out of 1 in 2,000 perchloride of mercury lotion. The mouth having been opened widely by a gag, the right cheek was split for a distance of two inches from the angle of the mouth. The ulcer could now be clearly seen, and its limits more carefully defined. A stout silk thread was passed through the left of the tongue at its posterior end; a similar suture was also put in the right half of the tongue. The mucous membrane of the dorsum was divided in the middle line. A pair of scissors then were used to cut through the soft palate close to the right margin of the uvula. All the posterior part of the soft palate was removed, together with the anterior pillar of the fauces and a part of the lateral pharyngeal wall. On the outer side the mucous membrane covering the median aspect of the alveolus was divided close to the last molar tooth. The mucous membrane of the floor of the mouth and the frænum linguæ were then divided, the incision being deepened so as to cut through the whole thickness of the floor of the mouth. The right and left halves of the tongue were next separated by scissors, and, by pulling on the silk sutures before mentioned, the affected half of the tongue was pulled upwards and forwards to such an extent that it was easy to divide the attachment of the tongue muscles close to the hyoid bone, and well behind the margin of the ulcer; thus the tongue, the floor of the mouth, and a portion of the palate were removed in one mass. The cut edges of the mucous membrane were approximated as closely as possible by interrupted sutures, especial care being taken to close the gap in the right half of the soft palate by passing the stitches deeply into the underlying muscles of this structure and those on the inner aspect of the ascending ramus of the jaw. Two drainage tubes were placed in the neck, one behind the sterno-mastoid, and the other at the lower end of the incision. The upper part of the wound in the neck was left widely open, one or two stitches being put in at the anterior and posterior ends; the remainder was lightly packed with gauze.

Mr. Legg remarked that in this patient the ulcer was in an unusual position, and he pointed out that it was the glandular enlargement which suggested to the patient the necessity of seeking advice. This is a not uncommon event, and so long as the ulcer or growth on the tongue does not cause inconvenience, it is very likely to be neglected, and the favourable time for operation passes. The patient often complains, as this one did, merely of the lump in the neck, and in all cases of glandular enlargement a very careful search for the primary focus of the disease must be made. This may be quite small—that is to say, the amount of ulceration may be slight, yet around the ulcer and in the substance of the tongue or wherever the growth is, there may be present a large indurated swelling. A good light, and the use of retractors for the cheek, and a tongue depressor, enables one to see the growth, which otherwise is invisible. A laryngoscope mirror is very useful in examining the back of the tongue. As regards the operation, Mr. Legg pointed out that the main thing to do was to remove the growth and glands as freely as possible; hence a good exposure of the parts was necessary, and he thought that splitting the cheek was very helpful when the growth was far back. The amount of deformity was very slight if care were taken to sew up the incision accurately, especially at the angle of the mouth. The incision must be made below the line of Stensen's duct, which should not be injured. In the removal of the tongue it was important to cut the muscles close to the hyoid bone, which could be satisfactorily done in the manner described, and when the growth encroached upon the floor of the mouth the muscles forming the latter structure must be removed. Of course, this leaves a large

wound communicating with the neck, and as there is always a certain amount of septic infection following these operations, the incisions in the neck must not be sewn up, at least in the upper part. If they are left open the large cavity granulates, and in the course of four or five weeks—sometimes sooner—it is completely closed. The amount of scarring in the neck is not greatly increased, and it is often difficult to say that the incision had not healed by primary union. Drainage tubes should always be placed in the dependent parts of the wound, for a few days at least. They may be removed in many cases on the fourth or fifth day.

The glands, and all the fascia covering the muscles, should be removed in one mass, and whenever they are adherent to the jugular vein this structure should be removed along with them. It is an unusual thing to find the glands adherent to the vein whilst the carotid vessels are free. Recurrence is most likely to take place in the glands at the upper end of the jugular vein, and hence especial care must be taken to remove these, which are close to the base of the skull, and beneath the upper end of the sterno-mastoid muscle.

Another point worthy of attention was the position in which the lingual artery was ligated—namely, a short distance from its origin. This was chosen because it was desirable to cut off the whole of the blood supply to the affected half of the tongue, which was to be removed close to the hyoid bone; so that the removal of the tongue is practically bloodless, and there is little risk of blood trickling into the larynx and lower air passages. When the lingual is tied in the usual place beneath the hyo-glossus, the dorsalis linguæ branch is not controlled, and much more bleeding from the tongue occurs. It has been said that ligature of the lingual so close to its origin is likely to be followed by secondary hæmorrhage. This had not been Mr. Legg's experience, and he thought the explanation lay in the fact that, by leaving the upper part of the neck wound widely opened, free exit for the discharges was provided, and any considerable septic infection of the neck wound was unlikely. In fact, the lower portions of the wound usually were healed in a week or ten days, and the upper portion was covered by healthy granulations. Ligature of the lingual artery in this situation also obviated the necessity of performing tracheotomy or laryngotomy, and the plugging of the upper opening of the larynx during the removal of the tongue.

Feeding of the patient was carried out through a nasal or œsophageal tube three or four times in the 24 hours, and the mouth was irrigated with 1 in 80 carbolic acid lotion.

The patient made an uninterrupted recovery.

## TRANSACTIONS OF SOCIETIES.

### ROYAL SOCIETY OF MEDICINE.

#### OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

MEETING HELD THURSDAY, DECEMBER 9TH, 1909.

The President, Dr. H. MACNAUGHTON-JONES, in the Chair.

DR. PHILIP D. TURNER, of Ryde, read a paper on ABDOMINAL HYSTERECTOMY SIXTY-THREE HOURS AFTER LABOUR FOR A NECROSSED AND SUPPURATING SUB-PERITONEAL FIBROID,

which will be found on page 658 under the heading of "Original Papers."

In the discussion of Dr. Turner's paper, Dr. LEWERS said that where acute symptoms arose after labour complicated by the presence of uterine fibroids, it was only in exceptional cases, such as the present, that hysterectomy was required. He referred to a case of labour at the eighth month complicated by fibroids he had recorded in which the patient had a rigor and high temperature a few hours before labour, and the temperature remained more or less high for

7½ weeks after delivery. Then a fibroid, the size of the fist, was expelled from the uterus with 15 oz. of extremely fetid pus, the patient making a good recovery. This patient was extremely anxious to have a living child, and unfortunately the child on the occasion referred to was stillborn. She was now pregnant again, and about to be re-admitted into the London Hospital for her confinement. There were still other fibroids in the uterine wall. When she was acutely ill after the last confinement, he had several times considered the question of hysterectomy, but had decided to defer it as long as possible, and the event had justified the expectant treatment adopted.

Mrs. BOYD thought that cases reported to the Section on previous occasions did not bear out the view that abortion would certainly have followed myomectomy.

Dr. HERBERT SPENCER congratulated the author on his successful treatment of the case. To have removed the tumour during pregnancy would have entailed great risk of abortion, and would have left behind a sub-mucous tumour much more likely to cause trouble than the sub-peritoneal growth, suppuration in which was a very rare occurrence. It had been happily dealt with by Doyen's total hysterectomy, which presented great advantages in these puerperal cases. He thought the suppuration occurred as the result of infection in removing the adherent placenta; no doubt the tumour had previously undergone necrobiosis. There was evidence of infection in the slough in the vagina, and a section of the small sub-mucous myoma at the fundus showed it to be deeply congested and inflamed.

Dr. TATE referred to a case of suppuration in a uterine fibroid, clearly due to infection at the time of delivery, which he operated on in October, 1906. Seven months previous to the operation the patient had a stillborn child at the eighth month. Subsequently a parametric abscess formed, and burst into the vagina. The patient continued to have a hectic temperature and steadily lost flesh. The fibroid tumour, which was of small size at the time of the confinement, steadily increased in size and was very tender. At the time of the operation abdominal hysterectomy was performed, the tumour being as large as a seven months pregnancy, and on incising it after removal three and a half-pints of stinking pus were evacuated, with a large sloughing mass of fibroid in the centre.

The PRESIDENT said there were two important questions raised in this case.

First, was the course pursued in the early period of the pregnancy the right one, and justified by the exploration of the tumour? Secondly, was the total hysterectomy called for under the conditions present after the labour? On both these points he was quite in accord with the treatment pursued.

The ample discussion which they had had during the last session in the Section showed that the plan of non-interference in similar growths during pregnancy was by far the wisest and safest for the woman and child. He also felt that the subsequent radical step taken, in face of the infective signs and symptoms, was the only course open to Dr. Turner. As to the examination of the tumour for the presence of pus—the stench disclosed at the time was to him (the President) sufficient evidence of the septic and infective nature of the tumour.

In reply, Dr. TURNER said that he did not think that there was any possibility of the patient's recovery by natural means. In reply to Dr. Routh, he agreed that infection at the time of labour might account for the acute symptoms: but that the necrosis and breaking down of the slough must have occurred during pregnancy; as such extensive and advanced changes could not have occurred within sixty-three hours. In reply to Dr. Stevens' doubt as to the fact of suppuration he could only say that the fluid was dirty yellow in colour, and had an excessively foul odour. In reply to Mrs. Boyd he said that his statement that myomectomy would inevitably have produced abortion was perhaps too absolute: but that the risk was certainly greater than he would have been justified in undertaking.

The discussion on Dr. Turner's paper was followed by a short paper on a case of

CYSTIC TUMOUR OF THE RIGHT BROAD LIGAMENT SPRINGING FROM THE UTERUS, AND APPARENTLY DEVELOPED FROM GARTNER'S DUCT,

by ARTHUR H. N. LEWERS, which will be found on page 659 under the heading of "Original Papers."

In the discussion that followed Mr. ALBAN DORAN referred to Unterberger's remarkable instance of a bilobed cyst of the right Gartner's duct, in which there were apparently two cysts, and on pressure on the left tumour sanious watery fluid issued from the os externum. The tumour was so intimately connected with the supra-vaginal part of the cervix that the uterus was removed as well. On dissection, however, it was found that the right one of the two cysts had a well-formed duct which ran through the wall of the cervix opening into its canal, whilst the left one also had a duct, but it opened into the right duct passing behind the cervix. In this case the ducts were saved, but unfortunately the patient was lost; in Dr. Lewer's case the patient recovered, but the cyst had been dissected off the uterus, and the ducts were therefore cut through. But in Unterberger's case there was long-standing infection before operation, the contents of the cysts being fetid, and in that exhibited this evening there could be little doubt that it was homologous to Unterberger's tumour.

Dr. AMAND ROUTH alluded to five cases of cysts developed from Gartner's ducts, which he had described in a paper read before the Obstetrical Society in 1894. (*Obst. Soc. Trans.*, Vol. XXXVI., 1894, p. 152.) His own case and those of Watts and Veit were cases of communicating vaginal and broad ligament cysts. In another, Milton's, Gartner's duct opened on to the antero-lateral wall of the vagina, and in Lawson Tait's case, both Gartner's ducts opened out in the vestibule on either side of the urethral orifice. In the latter cases probes could be passed into the broad ligament regions. He knew of no means of deciding whether a parovarian cyst was developed from Gartner's duct or from one of the vertical tubules of the parovarium, except from the way that the former tended to burrow also along the antero-lateral wall of the vagina. He asked for more evidence that Gartner's duct habitually entered the uterine substance.

Dr. DRUMMOND MAXWELL said that as Registrar to the Hospital, he had had the opportunity of examining the tumour, which at first sight had appeared to be an intra-ligamentous, fibroid undergoing cystic degeneration. It was only when sections were taken from its walls that its interesting origin was suspected, and he thought the evidence of the accompanying microscopic sections warranted the view that the tumour was of developmental origin, and arose in the intra-uterine portion of Gartner's duct.

Dr. BOYD was interested in the observation that the ureter was not seen. In a similar case of tumour, where a large cyst presented in the abdomen and burrowed deeply into the recto-vaginal septum down to the pelvic floor, wrapping the uterus round so that it appeared both in the anterior and posterior vaginal vaults, the ureter was stretched out over the outer abdominal surface of the cyst.

Dr. LEWERS thanked Mr. Doran for giving him the reference to Unterberger's case. It seemed to be a similar one to that recorded in his own paper. Unfortunately, Unterberger's case had ended fatally, and this seemed probably to have been due to his attacking the tumour from below first ineffectually, and later on having to deal with the tumour from above. Dr. Lewers thought it best to remove tumours of the kind by the abdominal route, as he had done in his own case. With reference to Dr. Routh's remarks, Dr. Lewers did not think he had quite appreciated the facts that the wall of the cyst was formed of uterine tissue, that it was connected by a stout pedicle of uterine tissue to the uterus at the level of the internal os, and that the small secondary cysts in the wall of the main cyst were lined by columnar epithelium.

Dr. HENRY ROSCOE, one of the best-known medical practitioners in North Staffordshire, died under tragic circumstances at Stoke on December 17th.

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

## SECTION OF MEDICINE.

MEETING HELD FRIDAY, NOVEMBER 26TH, 1909.

The President, WALTER G. SMITH, M.D., in the Chair.

## SPLENO-MEDULLARY LEUKÆMIA TREATED BY X-RAYS.

DR. MAURICE R. J. HAYES read a paper on above. Female, æt. 42, married; no children. Symptoms directly referable to her disease began in August, 1906, but the enlargement of her spleen was first apparent in December, 1908. In February, 1909, when X-ray treatment was commenced, she was very anæmic and wasted; she suffered much from breathlessness and palpitation, her legs were swollen, and she had hæmic murmurs. Her spleen extended for two inches to right of middle line, for three inches below umbilicus, and to the level of crest of left ilium. Liver slightly enlarged; no enlarged lymph glands. For purposes of irradiation the superficial area of the spleen was divided into four circular areas, ten centimetres in diameter, and each one was exposed in turn, a hard tube being used. The average duration of each exposure was eighteen and a half minutes. From February 20th to November 25th, 1909, twenty-two exposures were given. She had no treatment during July, August, September, and October, when she felt very much improved, and was able to perform her household duties. Her spleen had reduced in size till it was palpable for two and a half inches below the left costal arch, and it was freely movable. Palpitation, breathlessness and œdema had disappeared, and she looked very well—anæmia better. In the end of October her symptoms returned and X-ray treatment was resumed in November, to which she is responding. She has had no medicinal treatment whatever for her disease. She at no time in the course of treatment suffered from any general or local symptoms, which might be referred to the X-ray, save a slight dry dermatitis in April, when irradiation was suspended for three weeks. The reports on the blood-films, which were examined by Professor McWeeney and Dr. W. D. O'Kelly, are as follow:—

Dr. W. D. O'Reilly, are as follow:—					Hæmo- globin per cent.
		Reds.	Whites.	Myelocytes per cent.	
Feb.	15	3,100,000	566,000	20 of whites	60
March	1	—	704,400	—	—
"	23	3,528,000	209,333	10 "	63
April	5	4,368,000	197,000	17 "	58
"	24	2,224,000	172,000	7.3 "	63
June	21	5,072,000	36,000	8 "	75
Nov.	15	3,488,000	168,750	14.3 "	77

The PRESIDENT said that for himself, and he thought he was speaking also for his colleagues, he and they welcomed any treatment, even an empirical one, that promised to be of service in dealing with the disease. They had, however, to take into account the clinical fact that the disease was liable to very curious remissions, which would render the judgment of therapeutic success all the more difficult.

Dr. WATSON said he had treated five or six similar cases, and had generally exposed the spleen in six or seven areas. In his experience the treatment had not shown itself to be of very great value.

Dr. MCWEENEY said he had been immensely surprised, after having seen the state of the woman's blood in February, to see her the other day in such wonderfully good health. He examined her blood and noticed how very well formed the leucocytes were, and he could not find a single normoblast. Whether the change was only the partial recovery that one met with in such cases it was impossible to say. It was essentially a disease of the marrow, and how could they expect to benefit it by radiating the spleen?

Dr. HARVEY said the radiating of the bone-marrow had been discussed and tried, and in no case had it been anything like as successful as radiating the spleen. It had been suggested some years ago that

in the destruction of the lymphocytes and leucocytes which followed the radiating of the spleen there was a leucotoxin set free, which acted on the pathological cells formed. There was no doubt that the X-rays in general had a tendency to destroy cells of a pathological nature rather than normal cells, and it did not seem impossible that, once the process had commenced, bodies might be set free which could continue to have the same action on remote parts of the body.

Dr. BENSON said he had found that by treating the various parts separately dermatitis could be avoided. When a patient came back after a recurrence, it would be found that the tumour receded very much less quickly than on the first occasion, and in a case of long-standing, he had found it impossible to reduce the spleen at all.

Dr. PARSONS quoted a case of his own which was almost identical with Dr. Hayes' case. She was æt. 55, and had had a prolonged course of arsenic without any improvement. The condition of her white cells was almost identical at the end of the treatment with what it had been at the beginning. After the tenth or twelfth application of the X-rays a marked improvement took place in her blood, and the spleen decreased to such an extent that it was almost impossible to palpate it. She went away feeling perfectly well, but returned within a year's time with the spleen increased and a relapse in the condition of the blood. She again received benefit from the rays, but died in six months. It was quite certain that the rays effected a diminution of the spleen, but how it was brought about he did not know. The improvement in the blood was not brought about by the destruction of the white cells, although the rays might inhibit their formation.

Dr. ROWLETTE said he had performed a post-mortem last year on the body of a patient who had died of heart disease while under X-ray treatment. The leukæmia was discovered when she was put to bed in hospital, and as far as it was concerned, she had improved considerably. In the microscopic examination of the spleen he did not find any of the patches which were said to be typical of the disease, and it was possible that the X-rays had caused their disappearance.

Dr. HAYES, in reply, said he believed the woman's present condition to be due altogether to the X-ray treatment. Out of sixty-three cases collected and treated by the rays, only four were alive in from three to six years after the primary symptoms, so that it did not promise very well for the patient.

## SANE HALLUCINATIONS.

Dr. DAWSON read a patient's autograph account of above.

LIVERPOOL MEDICAL INSTITUTION.  
CLINICAL EVENING.

MEETING HELD ON DECEMBER 2ND, 1909.

The President, Mr. T. H. BICKERTON, F.R.C.S., in the Chair.

## DR. N. PERCY MARSH read a paper upon

## MODERN METHODS OF INFANT FEEDING

and introduced the subject by pointing out the importance of maternal nursing as a factor in the reduction of the present high infantile mortality. He then described the differences, both qualitative and quantitative, which exist between human and cow's milk, and the importance of the enzymes in nutrition and the consequent desirability of avoiding their destruction by the employment of sterilisation. He recommended Pasteurisation at 155° F. for the destruction of bacteria, and described Freeman's apparatus which he used for that purpose. He strongly advocated the percentage method of feeding especially in those cases of malnutrition in which the assimilative capacity of the infant had been impaired by previous improper methods. The details of percentage feeding were described firstly, when employed

through the agency of milk laboratories, and secondly the home methods as advocated by Holt in which, by the use of "top milk," containing 10 per cent., or 7 per cent. of fat variations to suit the requirements of any particular case could readily be made.

Cases illustrating the various methods employed were described and in conclusion he stated his belief that percentage feeding was far and away in advance of any method, which he had, in an experience extending over many years, previously adopted.

The paper was discussed by the President, Drs. Heatherley, O. T. Williams, H. Armstrong; and Dr. Marsh replied.

Medical cases were shown by Dr. R. J. M. Buchanan, Dr. A. Gordon Gullan, Dr. Nathan Raw, and Dr. Macalister.

Surgical cases by Mr. F. T. Paul.

Cases of diseases of children were exhibited by Dr. N. Percy Marsh, Dr. de Boinville, Dr. Peter Davidson, and Mr. R. C. Duggan.

Eye cases by Dr. Charles G. Lee, Dr. K. Grossmann, Mr. Edgar Stevenson, and Mr. Hugh E. Jones.

Ear cases by Mr. E. M. Stockdale.

Skin cases by Dr. Frank H. Barendt, Dr. Stopford Taylor, and Dr. R. W. Mackenna. The latter gentlemen also showed the new "Multostat," and demonstrated its uses in the treatment of diseases of the skin.

#### FRANCE.

Paris, Dec. 19th, 1909.

##### PERU BALSAM.

PERU BALSAM is, by reason of its comparatively high price, frequently adulterated.

Among the substances employed for this reprehensible practice may be mentioned alcohol, turpentine, copaiba, styrax, benzoin, but it is also fabricated by melting benzoin with castor oil.

Peru balsam is rarely employed internally, although its properties are identical with those of tolu balsam. It is reserved for external use, and in divers affections it has a marvellous effect. It is thus that it is used in the healing of contused wounds and torpid ulcers with good results; in the case of ulcers, associated with nitrate of silver, its action is much increased:—

Nitrate of silver, 6 gr.

Peru balsam, 1 dr.

Vaseline, 3 oz.

On the other hand, says Prof. Fleury, those who work in perfumery are well acquainted with the cicatrising properties of Peru balsam. When they cut themselves in the course of their work, it is with this product—used in the business—that they paint the wound, which heals rapidly without suppuration.

Certain practitioners use this drug in the treatment of complicated fractures. Dr. Suter, of Innsbruck, fills the wound with the balsam, and in more than two-thirds of the cases no suppuration was observed. During the Russo-Japanese War the Nippons treated the wounds by Peru balsam, and remarked that cases of tetanus were less frequent.

Besides its antiseptic and cicatrising properties, Peru balsam is an acaricide of great value, and is therefore used more and more for scabies. By rubbing all the body over with a simple pad steeped in the balsam, the acarus is killed in one *stance*, and without the necessity of taking a bath previously. The balsam is removed from the skin the following day by soap and an ordinary bath. Accidents due to absorption of the drug have never been noticed, at least not as regards adults. For children it is more prudent to abstain from using it in the pure state, but the following mixture may be prescribed:—

Peru balsam, 3 dr.

Liq. styrax, 5 dr.

Camphorated oil, 3 oz.

In certain cases, Peru balsam being expensive, and a quantity scarcely inferior to 5 oz. required for the operation, it may be advantageous from an economical point of view to employ a mixture in which the balsam enters for only a third part:—

Prof. Fleury frequently uses the following:—

Peru balsam, 5 dr.

Chloroform, 2 dr.

Vaseline, 2 oz.

WHOOPING-COUGH.

Among the best methods of treating the grave form of whooping-cough, inhalations of oxygen gas may be mentioned.

According to Dr. Weill, of Lyons, these inhalations are to be preferred to antipyrine or morphia, which often fail. They are specially indicated where the paroxysms are particularly grave and the child is threatened with broncho-pneumonia. In order that the inhalations may be efficacious, large doses should be given, from 15 to 20 litres, by means of the ordinary apparatus, the tube of which is attached to an ordinary funnel covering the face. At the slightest symptom of broncho-pneumonia the oxygen must be administered every hour.

The effect of the treatment is a marked attenuation of the violence of the paroxysms, although the number are rarely lessened. Very rapidly the cyanosis and dyspnoea diminish, while the state of prostration and somnolence between the attacks disappear, and anorexia is replaced by an excellent appetite. The children themselves understand the good effects of the inhalations, and ask for them at the moment of the paroxysm.

But one of the most patent and most interesting effects of oxygen is its influence on broncho-pneumonia, which it seems speedily to cut short, asepsifying, so to speak, the lungs.

##### OBSTINATE HÆMORRHAGE.

One of the best methods of treatment of obstinate hæmorrhage due to epistaxis, hæmophilia, hæmoptysis, intestinal hæmorrhage, is that of injecting antidiphtheritic serum once or twice a day in doses of 10 cubic centimetres. The results will be found always very satisfactory.

#### GERMANY.

Berlin, Dec. 19th, 1909.

##### A PROBLEM OF SEX.

At the Medical Society, Hr. P. Marcuse showed a child of six who had been brought up as a girl, but whose sex was now doubtful. The early onset of puberty was remarkable; from her fourth year the voice had become deeper, the pubic hair grew, but the mammae did not develop. Anatomically, the case could be called one of scrotal epispadias. Between two genital folds that might represent either the labia majora or ununited halves of the scrotum, was an erectile structure like the penis, at the root of which was the urethral opening. No trace of labia minora, vagina or uterus, or testicles was to be found. The pelvis was not of the female character, the hair of the head was long, the face not at all characteristic. The child's inclinations were rather those of a boy. Although he inclined to the opinion that the child was a male, he had advised the parents not to take steps to have any alteration made in the register until further observations had been made, regarding possible onset of menstruation, or seminal discharges showed, or evidence appeared of distinct sexual inclinations.

Hr. Gottschalk believed the child was a girl.

Hr. Rothmann advised a thorough examination of the nervous system, in order to determine whether there was any hypertrophy of the epiphyses, as had been suspected in similar cases.

At the Verein für Innere Medizin, Herren Langstein and Niemann discussed the

##### TISSUE CHANGE OF INFANTS DURING THE FIRST FOURTEEN DAYS OF LIFE.

They had determined that during the first few days

of life there was a considerable deficit of N., greatest about the third to the fifth day, and that after this the N. became gradually equalised. There was also an excessive excretion of chlorine and phosphorus in the first few days, and that this excessive excretion gradually declined. They endeavoured to determine whether this was due to the kind of feeding or whether it was physiological. For this purpose, the children were fed with expressed breast milk, but as this was poorer in colostrum than mothers' milk in nitrogen, the question had not been solved.

Hr. Niemann had examined the purin tissue change, in order to determine whether this had anything to do with the deficiency of N. As a matter of fact, the excessive excretion of N. was due to purin tissue change, as the excretion of uric acid in infants was very great during the first few days of life, and especially about the third day, and was a result of the destruction of leucocytes in the blood.

Hr. Rott rather assumed that the loss of weight that took place in new-born infants was due to loss of the watery parts, and caused by a condition of inanition that infants were in during the first few days.

Hr. L. Meyer agreed with Rott that the loss was owing to loss of fluid.

Hr. Gottschalk remarked that it was difficult to determine how much of the calories the new-born infant brought with it. In common with many other obstetricians, he had the child put to the breast at once, but the loss of weight took place just the same. A number of things contributed to this; there was the loss of warmth, the circulation, the digestive activity, and the intense activity of the organism. In his opinion, therefore, the loss of weight depended on other factors than those mentioned by the previous speakers.

Hr. Josef Hirsch drew attention to the weight curves that had been taken in the Israelitish Krankenhaus. Ten curves had been taken, seven of breast children, and three of children fed artificially. In the breast children the loss of weight corresponded to the meconium parted with. In the three others the loss was greater.

#### LUMBAR PUNCTURE IN CONVULSIONS.

Hr. Schiffer had observed the effects of lumbar puncture in four children in convulsions sufficiently well to form an opinion. The first case was one he saw first five years ago. It was a child, *æt.* 4, suffering from epileptic convulsions. These latterly had become almost incessant. The child was livid, and lay quite unconscious; 10 ccm. of fluid were taken away by lumbar puncture. The effect was perfectly striking. The convulsions gradually ceased, and the general condition underwent essential improvement. The second case was that of an idiot, *æt.* 5½, in whom the attacks began three years before, and gradually got worse, until they numbered 8 to 10 a day. The child lay in a perfectly apathetic condition. After the lumbar puncture the attacks became fewer, but returned again. On a second attempt at puncture the needle broke, but the attacks became fewer.

He had also done lumbar puncture not only when the status epilepticus was present, but with a view of reducing the severity of the spasms. He had had beautiful results in four cases (in one puncture was performed four times). In any case lumbar puncture might have a life-saving effect in convulsions, just as venesection in uræmia.

Hr. Eckert spoke of the good effects of lumbar puncture with subsequent sluicing with water in spasmophilia, whooping-cough, and also in eclamptic convulsions without whooping-cough that had been observed in Heubner's wards.

Hr. Cassel had seen two cases in which lumbar puncture was performed. The first case was that of a child of 10 months, with whooping-cough and convulsions, the latter very frequent; 20 ccm. of fluid were withdrawn, sluicing was done, and chloral hydrate given. The next day the attacks had increased to 27, and then ceased. The second case was that of a child of three months, with whooping-cough and convul-

sions. No fluid came away on puncture. The child died soon after from pneumonia.

Hr. Heubner remarked that lumbar puncture had gained new ground in pediatrics as symptomatic treatment in convulsions, where there was no disease of the brain, and also in psychoses without cerebral disease. In one case of meningitis recovery took place after it. It might have been a case of serous meningitis. Lumbar puncture must be made use of symptomatically, as it was not dangerous. Whether its effects were due to release of pressure was still questionable. In the case mentioned by Eckert as ending fatally the autopsy showed excessive hydrocephalus externus.

#### AUSTRIA.

Vienna, Dec. 19th, 1909.

#### CEREBRAL TUMOUR.

At the Gesellschaft f. Innere Medizin, Hochwart and Eiselsberg exhibited a case suffering from Jackson's epilepsy on which they had operated.

The patient, *æt.* 28, had suffered for the last two years from right-sided Jacksonian epilepsy. Since the 28th of November, 1908, the right side of the body has been noticeably weak and atrophic.

The reflex in the right extremities was greatly reduced while decided ataxia was present, with right facial paresis and congestion of the fundus of the eye. He was very irritable and violent, which was quite opposed to his nature before the illness. An area over the left ear was tender on percussion, though this space was no greater than a shilling.

Wassermann's reaction was positive, but a mercurial treatment gave no relief. From this it was concluded that the morbid growth was a gumma or some allied form of tumour.

On the 16th of October it was resolved to operate. After making the part as bloodless as possible by Esmarch's method, a flap was made above the ear, and the cranium entered. On opening the dura mater the surface of the brain was found perfectly healthy and normal in appearance. With the assistance of a feeble faradic current to the motor centres he soon discovered the active centre of the thumb, which happened to be the tender area. Here an incision was made in the surface, but only a centimetre below the knife struck a hard firm body about the size of a walnut, which was removed, and found to contain spindle-shaped cells thus resembling a sarcoma in structure. No drainage was provided for, and the dura mater accurately stitched, the wound was closed.

After the operation the entire right arm was paralysed, the right foot parietic, as well as the right facial nerve. Since that time the paralysis has slightly improved, still, the patient is worse at the present time than before the operation, and further improvement is hardly to be expected.

Teleky agreed with the conclusion of Eiselsberg that little hope of improvement can be held out to the patient now. He related a similar case he operated on for Gussenbaur, the operation did no good, but rather impaired the functions of the patient.

#### CONCRETIO PERICARDII CUM CORDE.

Redtenbacher presented a patient with an enlarged cardiac dulness extending beyond the sternum on the right side and a finger's breadth externally beyond the mammary line on the left and upwards above the third rib. The heart movement caused no displacement, while the sounds were clear though having a pendulum rhythm, but no murmur. The liver and spleen were both enlarged, the pulse rhythmical, though the wave on inspiration was less than in expiration. The conjunctival reaction with tuberculin gave a positive result, which led to the conclusion that the aetiology of the disease was tubercular, probably a tubercular concretion.

#### MYASTHENIA.

Algyogyi next brought forward a female patient, *æt.* 33, who had complained for more than a year of difficulty in deglutition, particularly after hard food that required chewing, as it would regurgitate by the nose in making an effort to swallow. After a short

time the masseter muscles also failed to act, having become tired or exhausted; when the patient had rested a short time she was able to resume her meal with comfort. The muscles of the extremities, the oral muscles, and the eyelids suffered in the same manner, but after a rest she could resume walking and talking as if nothing were the matter. Along with these myasthenic symptoms were also phenomena of hysteria, such as irregularity of the vocal cords, ovarian tenderness, rachialgia, loss of corneal reflex, left-sided hemianæsthesia for touch and pricking.

#### WASSERMANN'S REACTION.

Bauer criticised the value of Wassermann's test as a diagnostic for syphilis. He found that it often failed in undoubted cases of the disease. In visceral cases he admitted that it never failed in his experiments. He always took the blood from a vein, which has the advantage of obtaining the blood before oxidation or depuration commences. In the prognosis of syphilis he found the absence of enlargement of the spleen and galactosuria were favourable indications. In the therapy he specially drew attention to endarteritis luetica, which he thought should be checked at the earliest opportunity, as the valves and coronary vessels soon become involved in the general destruction, while aneurysms were no less important. Muscular injections and inunctions should be frequently repeated, which relieved the angina pectoris that often accompanied vascular changes. With negative Wassermann reactions years after infection with negative symptoms have always a favourable prognosis; but positive reactions with negative physical signs should be a serious warning to the attendant to beware of the future.

#### HUNGARY.

Budapest, Dec. 18th, 1909.

At the recent meeting of the Nagyvarad Medical Society,

Dr. Gross read a paper on

#### CHANGE IN THE AORTA IN SYPHILIS.

He discovered the following changes in several carefully studied cases of syphilis of the aorta. In the first recent case, thickening of the intima, consisting chiefly of spindle-shaped cells, imbedded in homogeneous, intercellular substance was marked. Portions of this thickened intima were made up of mucoid substance, and the superficial layers consisted of thick, hyaline fibres. In the adventitia there was, proliferation of capillaries, whose intima was thickened and adventitia infiltrated with round cells which extended into the media. Four more advanced cases showed cicatrised areas in the media where the muscle bundles were almost completely destroyed. The process in the adventitia no longer progressed and the fibres had become sclerotic. The thickened intima was also cicatrised and replaced by coarse connective-tissue fibres of hyaline appearance. The elastic elements of the aorta were more or less destroyed by breaking up into homogeneous flakes. The difference between syphilitic and ordinary aortitis is only quantitative. The diagnosis of syphilis can only be made, if distinct gummata have developed in the walls of the aorta.

#### ON THE ACTION OF IODIDES IN ARTERIO-SCLEROSIS

Dr. Revix said that although the use of this drug in the treatment of this condition is very extensive yet little is known of its mode of action. He presented the results of a series of observations in young men, otherwise healthy, to whom potassium iodide was administered in daily doses of from 0.3—0.60 grammes, for periods of ten to fourteen days. It has been claimed that this drug has no vaso-dilating action. Examination of the blood from the experimental subjects showed that there was a marked loss of viscosity, sometimes as much as ten per cent. This apparently explains most of the therapeutic effects of the drug, as its action in increasing the fluid character of the blood is equivalent to dilatation of the vessels, for the reason that the stream flows more

rapidly. This also shows that the drug must be continued for long periods in order to produce any effects. The serum does not become fluid to the same degree as the blood *en masse*, and sometimes is even increased in density, so that the change appears to be governed by the behaviour of the cellular elements of the blood alone.

Dr. Raiz read a paper on

#### THE RARER FORMS OF RHEUMATISM.

Some interesting comments were made by him on this subject. He believes that a sharp line must be drawn between muscular and joint rheumatism. To secure uniformity and to avoid confusion, the term muscular rheumatism ought to be dropped (first advised by T. Schreiber) and the word rheumatism applied to that inflammatory condition of the various locomotory organs and their appendages which results from sudden change of temperature. Persons inclined to rheumatism need not, therefore, fear intense uniform cold, but rather overheating, especially that brought about by muscular exertion, followed by sudden rest and cooling. The quickest and most reliable remedy in cases of fresh acute rheumatism, is exercise. The patient may safely indulge in all those movements which cause pain, but care should be taken to exclude joint rheumatism. Chronic rheumatism can only be cured by mechanotherapy in which active and passive movements play an important part. Among the rarer sites for rheumatism which are little mentioned in the literature, are the following: A rheumatic process in the periosteum of the ribs, the sternum, and the long bones; rheumatism of the diaphragm, isolated rheumatism of the coccyx, and the pelvic outlet; and localised rheumatism of the muscles of mastication. Instances of these were mentioned, and good results were secured in all, but that of the diaphragm, by forcible massage. For rheumatism of the diaphragm the faradic current gave some relief. A number of localities were mentioned which are favourite sites of the rheumatic process, mostly muscular attachments.

### FROM OUR SPECIAL CORRESPONDENTS AT HOME.

#### EDINBURGH.

ROYAL COLLEGE OF SURGEONS, EDINBURGH.—The usual annual dinner of the College was held on December 14th, opportunity being taken of the event to inaugurate the magnificent new hall which forms so important a feature of the recent extension of the College premises. Additional interest was lent to the occasion by the presence of Lord Rosebery, who proposed the toast of "The College" in one of his happiest speeches. He spoke of his only qualification for the position of proposer of the toast as being the descendant of Gilbert Primrose, the first recorded Fellow of the College, and brought with him Gilbert Primrose's mortar, which he (the speaker) had received from the town museum of Hawick. It is inscribed "Gilbert Primrose, Chirurgeon, 1569." Gilbert was one of the corps of volunteers enrolled in 1558 to defend the city of Edinburgh against their old enemies, the English, and it is supposed that he lost the mortar on the Borders in the exercise of his volunteering proclivities. A son of Gilbert, Duncan, was one of the surgeons to the Kings of Scotland, and other members of the same family were enrolled in the books of the College. Lord Rosebery then sketched the history of the College during the four centuries of its existence—the early barber-surgeons, with their monopoly of the manufacture of aqua vitæ, their differences with the apothecaries, and with the physicians, their final emergence into the dignity of a Royal College, and their contributions to the advance of surgery and medical education. He recalled that nine years after the reception of their original charter the anguish and disaster of Flodden fell on Scotland, and reflected that in the whole of history there was

nothing more eloquent and courageous than the proclamation of the Edinburgh Town Council after that battle. The news had got abroad in Edinburgh. The magistrates issued a proclamation. It was short and it was simple. It said that rumours were abroad that something had happened to the King and the Army at Flodden. They were not yet authenticated, but in the meantime they summoned every able-bodied citizen by toll of bell and beat of drum to come forward to the defence of the city, and in the meantime, they said, women must not be allowed to wail or weep in the streets. They must go to the churches and pray for the King, for the Army, and for their countrymen who were in the Army. The President of the College, Mr. J. M. Cotterill, in his reply, returning thanks to Lord Rosebery for his very eloquent speech, announced that at a meeting held on December 10th the Right Hon. Lord Rosebery had been elected an honorary Fellow. The secretary then handed Lord Rosebery his diploma, and formally called on him to sign the roll, whereupon the new Fellow was duly robed by the officer. In addition to the loyal and patriotic toasts, the toast list contained "The Houses of Parliament," proposed by the Lord Justice Clerk, and replied to, owing to the absence of Lord Balfour of Burleigh and Sir John Tuke, by Lord Rosebery, who took the opportunity of defending himself from the attacks of both political parties, and asking his critics to judge him by what he actually said, not by snippets of his Glasgow speech. Mr. George Berry proposed "The Universities and Sister Corporations," and was replied to by Principal Macalister and Mr. Lentaigne, President of the Royal College of Surgeons of Ireland.

**RECEPTION BY THE PRESIDENT AND FELLOWS.**—On Wednesday, the 15th, a most successful reception was given by the President and Fellows of the College, which was attended by about 1,200 guests. The arrangements were most excellent, and the new hall and other rooms were much admired. Lord Rosebery lent for exhibition the mortar which he brought to the banquet. Gilbert Primrose was the first known President of the College; he held the chair from 1581 to 1582, and also in 1602. He died at Westminster in 1616, at the age of 80, and it is recorded on his tombstone that "To the end of his life he was chief surgeon to the King, and died adorned with testimonies of public sorrow from Prince and People."

**MEMORIAL TO THE LATE PRINCIPAL CUNNINGHAM.**—To give expression to the feelings of esteem with which the late Professor Cunningham was regarded, a meeting was held on the 15th in the Court-room of Edinburgh University. Sir William Turner occupied the chair, and stated that he had sympathetic answers from the Lord Provost, Sir Donald MacAlister, Professor Reed, Aberdeen, and others. A resolution that some form of memorial be obtained to commemorate Professor Cunningham's work was adopted, being proposed by Mr. J. M. Cotterill, and seconded by Professor Crum Brown. Professor Henry Littlejohn said that Trinity College, Dublin, had decided to erect a medallion, and institute a medal in anatomy. It had been thought that the memorial might be a joint one, and the Dublin promoters offered the artist's drawings and dies for the use of Edinburgh. Professor Lodge and Professor Arthur Thomson moved that a committee be appointed to take the needful steps to carry out the objects of the resolution.

### BELFAST.

**DISCUSSION ON POOR-LAW REFORM.**—An interesting discussion on Poor-law reform and the medical questions involved in it was held on Thursday evening, December 16th, at a meeting of the Belfast Division of the British Medical Association, Dr. Chas. Kevin in the chair. The subject was brought forward in a paper by Dr. Andrew Trimble, who is a member of the Corporation and deeply interested in the question of social reform. He gave a brief sketch of the Report of the Royal Commission, and described the main differences between the majority and minority reports. All agree, he said, that the present system of Poor-law

relief must be abolished, and with it the mixed work-house system must go. But while the reforms proposed by the majority are individualistic, the minority report is markedly socialistic in character, and though he did not agree with all of it, Dr. Trimble thought it was certainly the most thoughtful part of the whole Report, and well deserved careful study. The chief suggestions of the Report were described, and the proposed County medical service discussed. In conclusion, Dr. Trimble asked the question, "Will there be legislation?" Some people, including officials, profess great scepticism in the matter, and say that no Act was ever born of a Report. On the other hand, both political parties are pledged to deal with the question, and the whole trend of public opinion is in favour of sweeping reforms in the present methods of helping the poor and infirm.

Sir John Byers held up the German system as a model, including as it does the three branches of insurance, accident, old age, and invalidity, each scheme having triple support, i.e., from the State, the employers, and the people. His objection to the scheme proposed in the Report was that it merely shifted the responsibility to another Board, and that not a directly elected one. He expressed his conviction that we were on the verge of wide-spreading changes, and said he was surprised that medical men, and especially Irish Dispensary officers, were so little scared by the prospect. One thing he regarded as quite certain, and that was that there would soon be a large increase in taxation.

Dr. John Campbell dwelt on the apathy of the dispensary medical men. Only two were present at that meeting, and it was most difficult to get most of them to take an interest in the matter. He preferred the scheme suggested by the Irish Vice-regal Commission, of a State Medical Service.

Dr. Cecil Shaw agreed with Dr. Campbell about the apathy of the men themselves, and mentioned the difficulty the Irish Committee of the British Medical Association, of which he is chairman, had experienced in getting answers concerning the exact amount of work done, distances covered, etc. Without definite information on such points it was useless to ask for reform, but no one would take the trouble to give it. As regarded a State medical service, it was clear that plan would not obtain much outside support, and the question they would have to answer was whether, failing a State service, they would support the plan of a County service.

Dr. R. M. Fraser expressed anxiety over the future of the dispensary officer, as the Report seemed to him to indicate that all his work would be re-distributed in such a way that no work would be left for him to do.

Dr. Irvine, Mr. R. J. Johnstone, and Dr. Buras also took part in the debate, and Dr. Trimble replied. The whole matter will be further discussed in the Ulster Medical Society, and probably at another meeting of the Division.

**INSANITARY AREAS IN BELFAST.**—At a special meeting of the Corporation held last week, a large improvement scheme was sanctioned, which will do away with the worst slums in the city, and provide sanitary dwellings in their place. The estimated cost of the scheme is £116,000, less estimated value of building ground and rents for buildings to be received, £66,000, making a net cost of £50,000. The scheme is the largest which has been undertaken in Belfast for thirty or forty years, and will be an untold benefit to the city. Incidentally, also, it will give employment to many labouring men for some years to come. As some of the areas are cleared they will be built upon, before others are interfered with, so that there will be no lack of accommodation.

**BABIES' CLUBS.**—At the annual meeting of the Belfast Branch of the Women's Health Association held last week, among other reports of an interesting and encouraging nature, the most so was that on the Babies' Clubs, four of which are now at work in the city. No less than 1,000 babies have become members.

and there is an average weekly attendance of 160. At each visit the baby is weighed, and weight entered upon a card, which the mother keeps. The mothers are encouraged to nurse their children, but if this is impossible they are taught the best methods of artificial feeding, and are supplied at small cost with good milk. Clothes are also supplied at the cost of the material, being made by ladies interested in the Clubs, and advice on health matters is given by the nurses and lady doctors who attend. The results have proved most satisfactory, and it seems that a small outlay in money, though at the cost of much unpaid labour on the part of the ladies interested, a great amount of benefit is being conferred upon the community, to whom healthy citizens are a valuable asset.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### ALLEGED LIBEL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your report of Dr. Martha Adams' plea for alleged libel, you state that I alluded to doctors as fee hunters, but that I did not go on to explain how it was that they vaccinated their own children. But in cross-examination I am only entitled to answer the questions put to me, and I presume that the Adams' counsel had not sufficient faith in the cow-pox brigade to press the matter further.

On ethics, I merely follow such masters as Schopenhauer, Herbert Spencer, and Jesus (see John vii. 8-10). Schopenhauer restricts the use of falsehood to the single purpose of self-defence, and I take it that saving your child from infection with the syphilitic inoculation, called vaccination, would come under this head. He also states, "the entirely unconditional and unreserved condemnation of lies, as properly involved in their nature, is sufficiently refuted by well-known facts. Thus there are cases where falsehood is a duty, especially for doctors." To my mind, doctors thoroughly, in fact far too thoroughly, appreciate this portion of their duties, but it is difficult in the witness box to discuss a well-known portion of ethics in replies to a hired legal luminary seeking to entangle you. The particular case my statement referred to was that of a parent in poor circumstances, whose child was refused admission into a hospital unless it had been vaccinated. In such a case as that, as I said, I consider an efficient substitute for truth to be perfectly permissible. But when it comes to fee-hunters, I have to decide whether they are too stupid to understand the real nature of cow-pox, or whether the desire for fees prevents them seeing this, and I take the latter view, though there are exceptions.

I am, Sir, yours truly,  
ERNEST POMEROY.

Campden House Chambers, W.

[We insert Mr. Pomeroy's letter, but must say that for his own sake it had better not have been written. The state of mind that persists in regarding syphilitic vaccination and vaccination as synonymous terms, and regards falsehood as excusable under certain circumstances, stands poles asunder from the scientific spirit, which is based upon accuracy and truth. Mr. Pomeroy's position is referred to editorially in the front part of our present issue.—ED., M.P. and C.]

### ON "BADLY-UNITED FRACTURE."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the interesting account of operation for above by Mr. Arbuthnot Lane, the screws used are called Wood's screws, as if designed by someone of that name. This is evidently an error, as the screw is called Wood screw in contradistinction to the Metal screws used for drawing together metal plates, is not pointed like the Wood screws, and quite a different

thread. "Every good surgeon should be a bit of a joiner," as the late Lawson Tait wisely said.

I am, Sir, yours truly,  
ALEXANDER DUKE.

London, W.

### POWERS OF THE GENERAL MEDICAL COUNCIL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—If your correspondent, a "Poor but Honest Practitioner," had read with any care the charges against the practitioner in the case to which he refers, which are printed in full on page 579 of your issue of December 1st, he would have seen that there was no question of a mere breach of Home Office regulations. It was a very painful case for the Council to have before them, and I imagine no single member gave his vote without deeply regretting the necessity for condemning a brother practitioner who had occupied for so many years an honourable position.

I am, Sir, yours truly,  
A MEMBER OF THE GENERAL MEDICAL COUNCIL.  
December 18th, 1909.

[The letter alluded to was inserted because we thought it right that our correspondent should be permitted to express his general views, which appeared to be, on the whole, sound. He was clearly wrong as to the particular penal case, as shown by the reports of the Council and by the above letter.—ED. M. P. AND C.]

## SPECIAL ARTICLES.

### THE BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH

WE have referred in another column of our present issue to the magnificent legacy by the late Mr. Alfred Beit, supplemented by the additional gift of his brother, Mr. Otto Beit, amounting to £215,000, for the furtherance of medical research in all its branches. Herewith we append particulars of the

#### DEED OF FOUNDATION.

This Indenture and Deed of Foundation made the tenth day of December, 1909, between Otto Beit, of 49 Belgrave Square, London, Esquire (hereinafter called "the Founder"), of the first part, and the Right Honourable Alfred Viscount Milner, G.C.B., G.C.M.G., the Right Honourable George Nathaniel Baron Curzon of Kedleston, G.C.S.I., G.C.I.E., the Right Honourable Richard Burdon Haldane, of 28 Queen Anne's Gate, London, K.C., M.P., the said Otto Beit, James Kingston Fowler, of 35 Clarges Street, Mayfair, London, M.D., and Bouchier Francis Hawksley, of 14 Hyde Park Gardens, London, Gentleman, of the second part.

Whereas the Founder is desirous as a Memorial to his brother, the late Alfred Beit, of 26 Park Lane, London, Esquire, of founding and endowing Fellowships with the objects and on the terms and conditions hereinafter contained and with a view thereto, has transferred to the four persons last-named parties hereto of the second part the investments specified in the First Schedule hereto, which are of the estimated value of £215,000, and should produce an annual income of about £7,525. Now in pursuance of the said desire

This Indenture witnesseth and the Founder hereby declares as follows:—

1. The objects of the Founder are to promote the advancement by means of research of medicine and the allied sciences in their relation to medicine, and to do so by founding and endowing Fellowships to be called "Beit Memorial Fellowships for Medical Research," and to be of sufficient annual value to provide for the adequate support of the Fellows so that, while holding the Fellowships, they may be able to devote their whole time to research.

2. In this Deed of Foundation:—

(i.) The expression "the Trustees" means the persons parties hereto of the second part or other the Trustees for the time being of this Deed of Foundation.

(ii.) The expression "the Advisory Board" means the Members for the time being of the Advisory Board hereinafter constituted.

(iii.) The expression "the Endowment" means the said investments specified in the said First Schedule and the investments of any additions made to the Endowment and the varied investments for the time being representing such investments.

3. (i.) There shall be a body of Trustees all of whom shall be men.

(ii.) The number of the Trustees shall be not less than five nor more than seven.

(iii.) A Trustee may retire at any time by written notice given to the others of the Trustees or on the appointment of a new Trustee in his place.

(iv.) Members of the medical profession, whether Members of the Advisory Board or not, shall not be ineligible for the office of Trustee, but the Trustees shall not appoint a member of that profession to be a Trustee if the appointment will make or continue the number of Trustees of that profession more than two.

(v.) The Principal for the time being of the University of London shall be one of the Trustees, but only while he shall hold the office of Principal.

(vi.) The following shall be the first Trustees, that is to say:—

The Right Honourable Alfred Viscount Milner, G.C.B., G.C.M.G.

The Right Honourable George Nathaniel Baron Curzon of Kedleston, G.C.S.I., G.C.I.E.

The Right Honourable Richard Burdon Haldane, of 28 Queen Anne's Gate, London, K.C., M.P.

H. A. Miers, Esq., F.R.S., the Principal of the University of London.

The Founder.

James Kingston Fowler, of 35 Clarges Street, Mayfair, London, M.D., and

Bourchier Francis Hawksley, of 14 Hyde Park Gardens, London.

4. (i.) The affairs of the Trust shall be administered by the Trustees.

(ii.) The income of the Endowment shall be applied by the Trustees:—

(a) In keeping such a balance at the Bank as they shall from time to time consider desirable.

(b) In payment of the costs charges and expenses of the Trustees and the costs charges and expenses of the Advisory Board and the members thereof and generally of the administration of the affairs of the Trust.

(c) In payment to the Fellows of their Fellowships and

(d) Any balance shall be applied by the Trustees to promote in such manner as in their uncontrolled discretion they shall think proper the advancement by research of medicine and the allied sciences in their relation to medicine but without imposing any obligation whatever on the Trustees it is the desire of the Founder that such balances be applied to the increase from time to time in the number of Fellowships.

#### THE ADVISORY BOARD.

5. (i.) There shall be an Advisory Board of men consisting of not less than five nor more than seven.

(ii.) A member of the Advisory Board shall hold office for five years and shall be eligible for re-appointment.

(iii.) Every member of the Advisory Board shall be a member of the medical profession.

(iv.) A Trustee being a member of the medical profession shall not be ineligible for appointment as a member of the Advisory Board.

(v.) A member of the Advisory Board may retire at any time by written notice given to the Trustees.

(vi.) The Board shall make such reports to the

Trustees as are herein provided for and perform such other duties as are hereinafter imposed on them.

(vii.) The following shall be the first members of the Advisory Board that is to say:—

Sir T. Clifford Allbutt, K.C.B., M.D., F.R.S., Regius Professor of Physic, University of Cambridge.

J. Rose Bradford, M.D., D.Sc., F.R.S., Professor of Medicine, University College Hospital Medical School, Secretary of the Royal Society.

James Kingston Fowler, M.A., M.D., D.Sc., Senior Physician to the Middlesex Hospital, late Dean of the Faculty of Medicine, University of London.

C. J. Martin, M.B., D.Sc., F.R.S., Director Lister Institute of Preventive Medicine.

William Osler, M.D., F.R.S., Regius Professor of Medicine, University of Oxford.

E. H. Starling, M.D., F.R.S., Professor of Physiology, University College, London, University of London.

6. (i.) The annual value of the Fellowships shall be £250 and there shall be as many Fellowships of that annual value as the income of the Endowment available for the purpose will suffice to pay so that initially there will be thirty Fellowships.

(ii.) Provided that if at any time the Trustees shall be satisfied that the annual value of the Fellowships is not sufficient or is more than sufficient to provide for the adequate support of the Fellows they may increase or (as the case may require) reduce such annual value and at the same time make the necessary alteration in the number of Fellowships but not so as to prejudice the rights of any then existing Fellow.

7. (i.) The tenure of a Fellowship shall be three years subject to determination by the Trustees at the end of the first or second year if in their judgment the work of the Fellow during the year does not justify the retention of the Fellowship.

(ii.) Provided that in exceptional cases the Advisory Board may on the application of a Fellow recommend the extension for a further period not exceeding one year of the Fellowship held by such Fellow. The Advisory Board shall report the recommendation to the Trustees with a statement of the reasons for the recommendation. The Trustees shall in their discretion have power to grant or not to grant the extension.

(iii.) The Trustees may in their discretion for what they shall consider grave cause suspend for such time as they shall think fit or remove any Fellow from his Fellowship.

8. (i.) Every Fellow shall be a person man or woman of European descent by both parents but otherwise of any nationality whatsoever who at the date of election shall have taken a degree in any faculty in any University in the British Empire approved by the Trustees or if female have passed the examinations which would have entitled her if male to take any such degree.

(ii.) Provided always that in exceptional cases the Trustees may if the Advisory Board shall so recommend accept the possession by a Fellow at the date of election of a medical diploma registrable in the United Kingdom as a qualification for election to a Fellowship in lieu of his or her having taken such degree or passed such examination as aforesaid.

(iii.) No person shall be qualified or disqualified for election to a Fellowship on account of his or her religious or medical opinions.

(iv.) Any candidate for a Fellowship who shall directly or indirectly canvass any of the Trustees or any Member of the Advisory Board shall be disqualified for election to a Fellowship.

#### ELECTION TO FELLOWSHIPS.

9. (i.) Elections shall be made:—

(A) In each of the first second and third years after the date of this Deed of Foundation to such

number not being more than ten of the Fellowships as the Trustees shall think proper to fill and in each of the second and third year elections may in addition be made to any casual vacancies among the Fellowships.

(B) In each subsequent year to all or such less number as the Trustees shall think proper to fill of the Fellowships vacant on the day of election.

(ii.) Elections shall be made on or about the 1st day of January in each year the first election however being made on or about the 1st day of March, 1910.

10. (i.) Before any election of Fellows notice (which shall not be less than three calendar months' notice except in the case of the first election for which one calendar month's notice shall be sufficient) shall be given by advertisement in the Press of the date of election of the number of Fellowships it is proposed to fill and the date by which and the persons by whom applications will be received.

(ii.) Candidates for election to Fellowships shall make written application for election. The applications of candidates shall give full information as to their qualifications academic standing and previous career and state the general character of the research which they propose to carry on and the place at which they propose to carry it on. Applications must be accompanied by the names of not more than three references one of which shall be the name of the head or some Professor Lecturer Dean or Tutor of the University or College or of any College of the University at which the candidate took his or her degree or if female passed such an examination as is referred to in clause 8 of this Deed of Foundation. Candidates who are not graduates of a University must give as one of these references the name of a Teacher under whom they have studied for their diploma. No testimonials must be sent or will be received. The applications will be considered by the Advisory Board. The Advisory Board after consideration of the applications will decide which of the candidates are qualified and fit to be elected and as to their relative merits and in considering such relative merits the Advisory Board shall have regard not only to the personal record of the candidates but also to the importance of the research work proposed by them and regard may also be had to such work in relation to work upon which other Fellows are engaged or which other candidates propose to carry on. The Advisory Board will then make and forward a report to the Trustees which shall contain the names placed in the order of their relative merits and shall include the names of all the candidates whom the Advisory Board consider to be qualified and to be fit to be elected without regard to the number of Fellowships to be filled and will with such report forward any recommendations made under clause 8 of this Deed of Foundation also any recommendation for extension made under clause 7 of this Deed of Foundation.

(iii.) On the day fixed for election the Trustees having first decided whether any Fellowships are to be extended under Clause 7 of this Deed of Foundation shall elect from the list forwarded as aforesaid such qualified persons—without regard necessarily to the order of their relative merits—as they shall think fit to the vacant Fellowships or to such of them as they shall think fit. In electing any Fellow the Trustees shall specify the work of research which he is authorised to carry on and the place at which he is authorised to carry it on.

11. (i.) In the Second Schedule hereto is contained a list of the recognised places of research.

(ii.) Provided that the Trustees may at any time after receiving a report from the Advisory Board remove any place of research from or add any place of research to the list aforesaid.

(iii.) Fellows may carry on research only at places of research included in the list for the time being of recognised places of research.

(iv.) Provided that the Trustees may at any time after receiving a report from the Advisory Board give permission to any Fellow in lieu of carrying on research at any of the recognised places of research to carry on research during a specified period of the tenure of his or her Fellowship at any Hospital College Medical School (including a School of Tropical Medicine) or Laboratory or other place not included in the list for the time being of recognised places of research.

#### DUTIES AND OBLIGATIONS OF FELLOWS.

12. (i.) Fellows shall devote the whole of their time to the authorised work of research and shall carry it on at their authorised places of research and shall not without the sanction of the Trustees take or hold any appointment whether paid or unpaid.

(ii.) Provided that any Fellow may with the previous sanction of the Advisory Board but not otherwise change his or her work of research and the place of research at which the work is to be carried on.

(iii.) No Fellow shall during the tenure of his or her Fellowship without the sanction of the Advisory Board enter or work for any examinations for any degree or diploma except such as is taken by the presentation of a thesis.

(iv.) At least one calendar month before the date fixed for the annual election of Fellows each Fellow shall furnish to the Advisory Board a detailed written statement of his or her work during the past year. These statements shall be considered by the Advisory Board who shall report thereon to the Trustees and make recommendations as to the approval or disapproval of such work and in the case of Fellows concluding the third year of their tenure and applying for extensions of their Fellowships as to such extension.

(v.) Provided that in any case in which the Advisory Board shall think necessary they may in order to enable them to better make such report and recommendations obtain expert advice on the work done by any Fellow but shall not in any year incur a greater expense in such advice than the sum placed at their disposal by the Trustees.

(vi.) Every Fellow who shall publish the result of his research in any form shall place immediately after his or her name upon the title page the following words "Beit Memorial Research Fellow."

13. Without prejudice to anything hereinbefore contained and in addition to all powers and authorities hereinbefore conferred on them the Trustees shall have the following powers and authorities:—

(i.) To appoint a new Trustee or Trustees.

(ii.) To appoint a new Member or new Members of the Advisory Board after receiving a report from the Advisory Board.

(iii.) To invest the Endowment or any part thereof in any investments for the time being authorised by law for the investment of trust funds with power to vary any existing or future investments for others of a nature hereinbefore authorised.

(iv.) In cases where investments cannot or cannot conveniently be held in the names of all the Trustees to make arrangements for the same being held in the names of some of them only.

(v.) To employ and pay a Secretary and such other officers clerks and servants as shall be necessary for the purposes of the affairs of the Trust.

(vi.) To hire or make other arrangements for an office whereat the affairs of the Trust may be carried on.

(vii.) To make vary and repeal regulations not inconsistent with this Deed of Foundation with regard to all or any of the following matters (that is to say):—

(A) Meetings of the Trustees and the quorum at any meeting;

(B) Meetings of the Advisory Board and the quorum at any meeting;

(C) The advertisement of elections to Fellowships and in what papers the advertisements shall appear;

(D) The election of persons to the Fellowships and the method in which their qualifications are to be ascertained;

(E) The suspension and removal of Fellows from their Fellowships and the extension of Fellowships;

(F) The method and time of payment of the Fellowships; and

(G) Any and every other matter with regard to which they shall consider regulations necessary or desirable.

14. After the expiration of the period of 20 years from the date of this Deed of Foundation a majority of not less than three-fourths of the whole number for the time being of the Trustees may from time to time (but during the lifetime of the Founder only with his written consent) revoke or alter any of the provisions contained in this Deed of Foundation (except in Clause 1 thereof) and make any new provisions in lieu thereof. Provided expressly that no such revocation alteration or new provision shall be in any way whatsoever inconsistent with any of the objects of the Founder as stated in Clause 1 of this Deed of Foundation.

In witness whereof the parties hereto have set their hands and seals the day and year first above written.

#### RECOGNISED PLACES OF RESEARCH.

1. The Physiological Laboratory of the University of London, South Kensington.
2. The Institute of Physiology, University College, London, University of London.
3. The Laboratories of the Departments of Chemistry, Biology, Physics, Anatomy, Pharmacology, and Hygiene, University College, London, University of London.
4. The Laboratories of the Departments of Chemistry, Biology, Physics, Anatomy, Physiology, Pharmacology, and Hygiene, King's College, London, University of London.
5. The Brown Institution, University of London.
6. The Laboratories of the Royal Naval Medical Service, Haslar Hospital.
7. The Laboratories of the Royal Army Medical College, Millbank, London.
8. The Lister Institute of Preventive Medicine.
9. The Laboratories of the Imperial Cancer Research Fund.
10. The Cancer Research Laboratories of the Middlesex Hospital.
11. The Laboratories of the Royal Commission on Tuberculosis.
12. The Laboratory of the London County Asylum, Claybury, Woodford Bridge, Essex.
13. The London School of Tropical Medicine, Victoria and Albert Docks, London.
14. The Liverpool School of Tropical Medicine.
15. The Laboratories of the Royal Institute of Public Health, 37 Russell Square, London.
16. The Laboratory of King Edward VII.'s Sanatorium, Midhurst, Sussex.
17. Such Hospitals and Medical Schools as are schools of the University of London in all the departments of their work.
18. Such Hospitals, Colleges, Medical Schools (including Schools of Tropical Medicine), Laboratories, and other places as may be approved by the Trustees after receiving a report from the Advisory Board.

The form of application for a Beit Memorial Medical Research Fellowship requires the applicant to state, in addition to personal details and references, his or her degrees or medical qualifications, education, general as well as scientific and professional, distinctions gained, original contributions to science or medicine, present occupation, and the general character of the research proposed to be undertaken.

A GRAND PRIZE (Highest Award) has been conferred upon Messrs. Burroughs Wellcome and Co. for their exhibit of "Tabloid" and "Soloid" brand products and "Wellcome" brand chemicals, at the recent Alaska-Yukon-Pacific Exposition, held at Seattle.

## REVIEWS OF BOOKS.

### MEDICAL MORBID ANATOMY. (a)

THE object of this volume is "to provide students with a concise account of the morbid anatomy of medical diseases, and enough pathology to explain the lesions described." Several excellent books have been written on surgical pathology, but hitherto no small work dealing with purely medical pathology has been written. We, therefore, welcome the handy manual under review as supplying a definite want in medical literature. As a companion to ordinary text-books on the practice of medicine it will be found invaluable. The descriptions given of the pathology and morbid anatomy of the various diseases mentioned are necessarily short, but still they are sufficient for the practical needs of students, for whom the book is primarily intended. The writers have drawn largely from their own somewhat extensive experience, and the statements made are characterised by general thoroughness and accuracy, which make the book a reliable one in every respect. For the convenience of students attending St. Bartholomew's Hospital, marginal references are given to specimens in the museum attached to that school, but we doubt very much the advantage of this arrangement. Practitioners whose knowledge of pathology has become somewhat rusty cannot do better than study this book, which forms an excellent introduction to the subject, and certainly contains all the information the student of medicine requires, not only to fit him for the final examination, but for the practice of his profession. We congratulate the authors on the publication of a book which possesses more than ordinary merit.

### MILITARY SANITATION IN HOT CLIMATES. (b)

MAJOR BLACKHAM's book has 143 pages, and deals with military sanitation in a clear and practical manner, and as the preface suggests is worded in a way suitable not only for "use to officers presenting themselves for examination for promotion in subject (J.), but also of real utility to the readers and their men when that desideratum of the soldier's life arrives, namely, "active service." For this purpose the book will be useful. In the next edition something about other blood-sucking flies, beside the mosquito, will no doubt find a place. The book is dedicated, with permission, to Lieut.-General Sir James Willcocks, K.C.M.G., C.B., D.S.O., whose experiences in West Africa have no doubt gone far to develop his sympathetic attention to medical matters.

### DICTIONARY OF OPHTHALMIC TERMS. (c)

THE author of this booklet tells us that his aim has been to make it a convenient, useful reference for the "busy practitioner" and the medical student, many of the terms not being found in the ordinary medical dictionary. All dictionaries, as Mark Twain says, "have to draw the line somewhere," and medical dictionaries find it necessary to leave out words relating to special subjects for which there is little or no use. At random some of this may be mentioned: "ablepsia," "achlys," "amphiblastoiditis," "caligo," "copiopia," "duscitas," "opsionosis," "Rhenis," "Taraxis," "Tylosis"—for the explanation of these terms the reader must refer to the author's book. For the rest, we notice that he describes

(a) "Medical Morbid Anatomy and Pathology." By Hugh Thurnfield, M.D., F.R.C.P., Senior Demonstrator of Medical Pathology, St. Bartholomew's Hospital, etc., and Wm. F. S. Branson, M.D., M.R.C.P., Junior Curator of the Museum, St. Bartholomew's Hospital. Pp. viii., 262. Crown 8vo. London: H. K. Lewis. 6s. net.

(b) "Military Sanitation for Soldiers serving in Hot Climates." By Major Robert J. Blackham, D.P.H. Lond., R.A.M.C., of the Middle Temple, Barrister-at-Law, Honorary Associate of the Order of St. John, Divisional Sanitary Officer, First Division, Indian Army; Fellow of the Society of Medical Officers of Health, and of the Royal Institute of Public Health; Member of the Royal Sanitary Institute. Bombay: Thacker and Co., Ltd. London: 1909.

(c) "Dictionary of Ophthalmic Terms, with Supplement." By Edward Maglalis, M.D., D.P.H. Bristol: John Wright and Sons, Ltd.

"nyctalopia" as day blindness, and "hemeralopia" as night blindness—definitions which are thus given in German and American text books—whereas in this country the interpretation of the terms is used in exactly the opposite sense. The confusion thus caused has mostly led English ophthalmic surgeons to discard the classical expressions, and use instead the English synonyms only, namely, day blindness and night blindness. Again, "onyx" is not now properly described as "pus between the layers of the cornea"—nor does the explanation of "Franklin lenses the same as bifocal," convey what is meant by this noun of optical contrivance. In a supplement the author adds some practical notes on testing the vision, the ordering of glasses, etc., and gives some useful formulæ for the treatment of the commoner varieties of diseases of the eye. The author has evidently expended a good deal of trouble in making a complete dictionary of ophthalmic terms—with some of which it would not be difficult for a student to puzzle, even would it be difficult for his teacher to explain them offhand.

#### GALL-STONES, THEIR COMPLICATIONS AND TREATMENT. (a)

WE welcome the appearance of this little book on gall-stones, for the reputation of the authors ensures that the subject will be presented in the most practical and up-to-date way.

The authors have endeavoured to present as briefly and yet as clearly as possible both the medical and surgical aspects of cholelithiasis, and also the complications to which the presence of gall-stones may give rise. We congratulate the authors on the way they have succeeded in their object, for the book is not only pleasant to read, but interesting and instructive. We feel sure that it will prove useful, not only to the practitioner but also to the student, for, notwithstanding the excellent way it is illustrated and turned out, the price should bring it within the reach of all.

We have only one small suggestion to make, and that is in reference to Cammidge's "pancreatic reaction," which is referred to several times, but possibly owing to the modesty of one of the authors the actual test is not described. We think that a description of this characteristic sign would not be out of place, for the book is sure to fall into the hands of some who may be unfamiliar with the test.

#### DISEASES OF THE EAR. (b)

IT is a pleasure to welcome the fourth edition of such a popular otological text-book as that before us, and it is additionally a matter for congratulation to find that such a well-known otologist as Dr. Thos. Barr has so talented a son to assist him in its production and to perpetuate a name so honoured in aural surgery.

The plan of the book follows that of its predecessors, and is much enhanced by many additions, particularly by the excellent coloured plates.

There are, however, several matters to which we would direct the attention of the authors with a view to addition, modification, or correction in the fifth edition.

In the directions for passing the catheter, there is no mention of the importance of never performing this manipulation except with the aid of the diagnostic tube. We are, however, glad to see that the dangers of Valsalva's method are well emphasised.

The section devoted to functional tests might well be enlarged. It is a pity that the watch is recommended as a test, and we cannot agree that the "chief value" of the acoumeter is for those who cannot hear the watch. Rinne's valuable test is dismissed in far too short a manner, and no mention is made of Lake's

work upon the subject. We are surprised, too, to find that testing is advised *before* physical examination, a foolish recommendation which, if followed, causes much waste of valuable time.

In discussing *paracusis Willisii*, no mention is made of Liebermann's explanation, which is, perhaps, the most likely yet advanced.

We are glad to find that the authors no longer considered sclerosis as an inflammatory disease, but as a separate pathological condition. It is a matter for surprise, however, that the work of their distinguished fellow-townsmen, Albert Gray, is passed over in silence.

The chapter upon diseases of the internal ear is very meagre, and would well bear extension. A paragraph is devoted to operations for the relief of vertigo and tinnitus, in which the authors appear to be unaware that Ballance's case of division of the auditory nerve was a failure, and have overlooked Yearsley's completely successful case of destruction of the cochlea.

Despite these criticisms, we must cordially congratulate the authors upon their "Manual," which, if not likely to be of much value as a work of reference, cannot fail to be popular as a text-book for students and practitioners.

#### DISEASES OF THE THROAT. (a)

AFTER a lapse of fifteen years since the first edition of this book, we welcome the second edition, which appears in a considerably enlarged form. This increase in the size of the volume has been necessitated by the giant strides which have been made in this special branch of surgery during the past decade and a half. The author introduces his book with a minutely detailed description of all the modern methods and technique of laryngoscopic examination, including the more recently devised apparatus of Killian and Brünning for direct laryngoscopy and bronchoscopy.

In each section of the book classification, ætiology, symptoms, differential diagnosis, prognosis, and treatment, therapeutical and surgical, all in turn receive appropriate consideration. The pathology—the final court of appeal in all medicine—of the various affections of the throat with which the book deals is carefully discussed. It receives the attention which is due to the pathology of all diseases, no matter where located, and which is essential for their rational and successful treatment.

In each chapter the author cites cases which have come under his own observation in illustration of the description in the text. These, though they add somewhat to the bulk of the book, serve as concrete typical examples of the course of the diseases and the line of treatment to be adopted, adding at the same time a living reality to the facts stated in the book. One of the most salient features of Dr. Downie's work is his dogmatism. In one important particular, however, many will dissent from the teaching of the author. While he strongly recommends chloroform anæsthesia for the removal of tonsils and adenoids, we would as urgently advocate the employment of gas and ether for inducing anæsthesia, particularly when, as is so frequently the case in practice, the thorough preparation of the patient may not be efficient. The differential diagnosis of tumours, benign and malignant, from syphilitic and tubercular affections of the larynx is dealt with in a careful and explicit manner, and the advantages and disadvantages of the several methods of their treatment are fully discussed.

The chapters in which the motor and sensory neuroses of the larynx are considered provide interesting and instructive reading.

Both students and practitioners will find the section on therapeutics extremely useful, and full of suggestions for the proper treatment of the inflammatory conditions of the throat and larynx, which are fully set forth in the earlier chapters of the book.

(a) "Gall-Stones, their Complications and Treatment." By A. W. Mayo-Robson, D.Sc., F.R.C.S., and P. J. Cammidge, M.D. Oxford Medical Manuals: Henry Frowde and Hodder and Stoughton. Price 5s. net. 1909.

(b) "A Manual of Diseases of the Ear." By Thos. Barr, M.D., and J. Stoddart Barr, M.B., Ch.B. Fourth Edition. Glasgow: Jas. Maclehoose and Sons. 1909.

(a) "Clinical Manual for the Study of Diseases of the Throat." By James Downie, M.B., F.F.P.S.G., Lecturer on Diseases of the Throat and Nose, University of Glasgow; Surgeon for Diseases of the Throat and Nose, Western Infirmary. Glasgow: Jas. Maclehoose & Sons.

## LITERARY NOTES.

We have received a copy of Herbert Fry's well-known guide to the London Charities. It forms an indispensable reference book to hospital secretaries and all interested in philanthropic work. An interesting preface contains a summary of the year's work, and an account is given, without comment, of the petition sent to the Chancellor of the Exchequer, with a view of modifying the adverse effects likely to follow the new methods of taxing land and of estates generally. It may be remarked, in passing, that such a consideration is hardly likely to be allowed to interfere with the application of financial principles approved by the legislature. A huge mass of details has been brought together, and so far as we have been able to test it, the information conveyed is of an accurate nature. The price is eighteenpence, and the publishers are Messrs. Chatto and Windus.

\*\*\*

We have been favoured with an unusual number of "Annuals" at this season, some especially designed for the medical profession, others for general use, and one or two for special purposes. In the latter category may be classed "The Englishwoman's Year Book and Directory," 1910, edited by G. E. Mitton, and published by Messrs. A. and C. Black, Soho Square, London, at price 2s. 6d. net. As its title implies, it is specially for the use of women, and contains invaluable information in regard to any career open to them. The mass of information in regard to the position of women in municipal, industrial and social life can probably be found nowhere else. The book has been called the "Woman's Whitaker," and well merits the title, but it is more than this, for, besides all usual information, there is much not to be found in Whitaker or any other reference book.

\*\*\*

AMONG the Christmas literature that has reached us, we would draw special attention to "Everybody's Story Magazine," published by the S.P.C.K. Society at 4 Bouverie Street, London, at the modest price of 4d. It consists of nine complete stories by well-known writers, full of healthy and stirring anecdote. "The Butler and Hero" may be taken as a remarkable story of the Boxer rising and the forcing of the renowned Pekin Gate by the allied armies, which grips one by its rehearsal at the dinner-table as if a present witness of the heroism of the little Japanese band, whose names are now honoured as immortals in that interesting country.

\*\*\*

We have received a neat and attractive little pamphlet from Messrs. the J. R. Riedel Co., of London. It contains brief notices of the eight preparations with which the name of that firm is associated. Aperitol comes first on the list. It combines the aperient principles of phenol-phthalein with a sedative valerian principle, thereby avoiding the pain that often goes with the former drug. Gonosan is a well-known remedy for acute gonorrhœa. It consists of a combination of oil of sandalwood with resin of Kava-Kava (the root of *papa methysticum*), which is said to exert a specific anodyne action on the mucous membrane of the whole urinary apparatus. It is put up conveniently in capsules. Thiol is a dark brown powder (or alternatively a liquid), which has a desiccative and astringent action on the skin; useful in psoriasis, erysipelas, and other affections of the skin. The rest of the remedies noticed have each a practical value to the practitioner. Any medical man can obtain a copy by writing to the J. D. Riedel Co., 54 Cannon Street, London.

## NEW PREPARATIONS.

We have received from Messrs. Parke, Davis and Co. specimens of

### CHLORETONE GAUZE.

Chloretone has been widely employed for application to wounds either as a dusting powder or as a solution

for saturating dressings), for the healing of which its analgesic and antiseptic properties have proved very helpful. It is thought, therefore, that the provision of Chloretone Gauze ready for immediate use will be a welcome addition to the armamentarium of the surgeon and general practitioner. Chloretone Gauze is saturated with a ten per cent. solution of the chemical (a derivative of chloroform and acetone) and is supplied in sterilised glass jars provided with air-tight caps, each jar containing one square yard of the moist gauze. The same manufacturers send us

### FORMIDINE GAUZE.

This new surgical dressing possesses powerful antiseptic properties, and may be used in place of iodoform gauze, with the advantages of freedom from unpleasant odour and liability to stain. It is prepared by treating sterilised gauze with a five per cent. suspension of Formidine, which chemical is a condensation product of iodine, formic aldehyde, and salicylic acid. In contact with organic alkaline secretions, Formidine slowly dissolves and develops the germicidal activity of its constituents. It is packed in sterilised glass jars provided with air-tight caps, each jar containing one square yard of the moist gauze.

### FRIARY INVALID STOUT.

We have examined "Friary Invalid Stout," as made by the Friary, Holroyd and Healey's Breweries, Ltd., of Guildford, and we find it to be a well-brewed malt liquor in which the high percentage of malt extractives is a distinct dietetic advantage over ordinary stouts. The proportion of proteins in these extractives is satisfactorily high, and we found the stout to be in good condition. The taste is free from acidity, and is pleasing to the palate. Our analysis showed the stout to have the following composition:—

Extractive matter	...	7.23 per cent.
Proteins	...	0.49 per cent.
Mineral matter	...	0.35 per cent.
Alcohol (per cent. by volume)	...	6.02 per cent.
Alcohol (as proof spirit)	...	10.54 per cent.
Volatile acid (as acetic acid)	...	0.04 per cent.
Fixed acid (as lactic acid)	...	0.16 per cent.

We found no preservatives present, and the general characters of the stout are such as to allow it to be recommended to those under medical care, with confidence.

## MEDICAL NEWS IN BRIEF

### Diseases of Occupations in Factories and Workshops.

THE total number of cases of poisoning and of anthrax reported to the Home Office under the Factory and Workshops Act during November, 1909, was 58, consisting of 53 cases of lead poisoning, 3 of mercurial poisoning, and 2 of anthrax. In addition, 20 cases of lead poisoning (6 of which were fatal) were reported during November among house painters and plumbers.

During the eleven months ended November, 1909, the total number of cases of poisoning and of anthrax was 581, as compared with 682 in 1908. The number of deaths during the same period was 37 as against 39 in 1908. In addition, there were 221 cases of lead poisoning (including 43 deaths) among house painters and plumbers during the first eleven months of 1909, as compared with 214 cases (including 36 deaths) during the same period of 1908.

### Health for the Army.

THE Director-General of Army Medical Services is able to record increasing improvement in the health of the Army, a great decline in the constantly-sick rates, a consequent addition to the effective strength, and a corresponding decrease of expenditure in the non-effective vote. During the ten years 1899-1908 the fall in the constantly-sick rates is calculated to have added 5,776 men to the effective strength, while the wastage through death and invaliding has been re-

duced by 2,900 men per annum. The admission age is eighteen, but in the case of boys who enlist in the Special Reserve at seventeen, and are transferred to the Line at seventeen-and-a-half, the youthfulness is acknowledged. These young fellows may be healthy, and may not often appear on the sick list, but they are not sufficiently mature for foreign service, and they are not so remunerative as the more seasoned men who are sought for. Sir Alfred Keogh's report discusses these and other questions concerning the health of the Army. Of course, under a voluntary system we cannot choose recruits as we would.

#### Large Bequest for Medical Research.

DR. CHARLES GRAHAM, of The Reculvers, Hastings, and formerly of Berwick-on-Tweed, at one time Professor of Chemistry at University College, London, and closely identified with the Society of Chemical Industry since its formation, who died on November 13th, aged 74, left estate valued at £47,782 17s. gross, with a net personalty £47,443 7s. 4d.

Subject to various bequests, the testator left the residue of his estate, probably about £35,000, to the Senate of the University of London, to found a fund to be known as the "Charles Graham Medical Research Fund."

#### Medical Certificates.

IN Rothesay Sheriff Court, on December 16th, continuation of proof was asked in a case from Arran on account of the illness of one of the parties. A letter from a medical man was produced to the effect that the man was unable to attend the court. Sheriff Martin said this could not be accepted as a certificate, not being "on soul and conscience," and was not such as might be expected even from an Arran doctor. While he would grant the continuation in this case, he wished it to be clearly understood that in future the Court would not consider medical certificates which were not in proper form.

### PASS LISTS

#### Cambridge University.

THE following candidates have passed the First Examination for Medical and Surgical Degrees.—Part III.—Elementary Biology.—J. C. Andrews, K. B. Bellwood, J. L. Davies, H. S. Evans, H. A. C. Goodwin, C. H. Gow, W. B. Loveless, R. D. Marett-Tims, E. W. Mason, H. L. Milsom, E. G. D. Murray, H. R. Pollock, E. J. Selby, T. H. Somervell, G. S. Trower, C. C. A. Whitworth, W. R. Wilson, and F. B. Winfield.

The following candidates have passed the Third Examination for Medical and Surgical Degrees.—Part I.—H. C. Attwood (Ds), G. V. Bakewell (Ds), T. E. Banister (Ds), D. C. Bluett, H. T. H. Butt (Ds), J. W. H. Chun (Ds), E. B. Clayton (Ds), H. F. Comyn (Ds), H. J. Couchman (Ds), C. H. Crawshaw (Ds), H. J. M. Cursetjee, J. Ellison (Ds), G. V. Fiddian (Ds), D. J. Freyer, A. W. Gaye (Ds), A. C. Gemmell (Mag.), J. B. Hance (Ds), G. G. Johnstone (Ds), R. F. Jones, G. L. Keynes (Ds), J. C. Marklove (Ds), R. W. Meller (Ds), H. J. S. Morton (Ds), F. C. Newman (Ds), A. B. Paul (Ds), M. N. Perrin (Ds), C. Raymond (Ds), E. Rayner (Ds), H. S. Reed (Ds), E. D. W. Reid (Ds), H. B. Richmond (Ds), F. H. Robbins (Ds), L. T. Rutherford, I. Singh (Ds), F. B. Smith (Ds), W. F. Thompson (Ds), J. R. Waddy (Ds), F. W. Watkyn-Thomas (Ds), H. B. Weir (Ds), H. F. Wilson (Ds), J. Winterbotham (Ds), and C. Worster-Drought (Ds).

The following candidates have passed the First Examination for Medical and Surgical Degrees.—Part II.—Physics.—J. C. Andrews, L. W. Batten, A. B. Bratton, B. Burnside, A. O. Courtis, C. D. Day, H. S. Evans, G. L. Ferguson, H. Gardiner-Hill, H. L. Garson, E. A. Gibb, C. C. Goodall, H. A. C. Goodwin, C. Grantham-Hill, E. T. Halnan, J. B. Hunter, R. W. P. Jackson, C. E. Kindersley, E. A. Leek, K. Masson, E. G. D. Murray, D. F. A. Neilson, W. D.

Newcomb, S. D. Nurse, A. V. O'Keeffe, W. Raffle, G. B. Sellwood, E. W. L. Sharp, W. G. Thompson, G. S. Trower, W. L. Willett.

#### The University of Sheffield.

THE Council, at its last meeting, made the following appointment:—Mr. Graham Simpson, F.R.C.S., to the Lectureship in Operative Surgery. At the same meeting the Pro-Chancellor (Mr. George Franklin) and the Vice-Chancellor (Sir Charles Eliot) were appointed representatives of the University on the Executive Committee of the Modern University Congress.

#### Conjoint Examinations in Ireland.

THE following candidates have passed the examinations of the Royal College of Physicians and the Royal College of Surgeons:—

Preliminary.—S. H. Bannerman, W. J. Broderick, A. F. Carbury, J. Daly, T. Flynn, J. Fox-Russell, G. P. Hely, J. J. Hutton, M. J. B. Kennedy, Miss M. Lees, P. S. McCabe, A. Macauley, J. A. Musgrave, J. O'Carroll, E. O'Keeffe, F. J. Power, A. Porter, G. M. C. Powell, F. J. Robinson, N. A. K. Sparrow, T. H. Sarsfield, W. J. Sweeney, H. J. Swan, P. W. Walsh, S. Weinstock, L. E. Wigoder, R. H. Newman.

First Professional Examination.—J. P. Brennan, B. J. Cusack, J. J. L. Cox, H. A. S. Deane, E. G. Foley, A. B. Foott, R. F. J. Griffith, R. Green, J. F. Lyons, D. McEntire, R. J. May, C. J. O'Carroll, H. V. O'Donoghue, P. Rowan, T. F. Ryan, G. N. Smyth, R. Tivy.

Second Professional Examination.—M. J. Ahearn, A. J. Best, C. M. G. Campbell, T. J. Kelly, D. Murphy, G. Sheehan, G. A. Shiel, W. Waugh.

Third Professional Examination.—F. M. J. Byrne, T. Farrell, M. Golding, E. Holden, F. Hannigan, F. P. Kennedy, P. B. Kelly, N. Keating, A. G. MacIlwaine, W. G. Maguire, P. H. McDonough, C. Molan, B. O'Donnell, T. P. O'Reilly, T. F. O'Donnell, K. O'Sullivan, J. B. Power, L. C. Rorke, P. Ross-Todd, J. V. Ryan, L. W. Roberts, J. C. Scanlan.

Final Professional Examination.—S. J. Barry, R. Charles, W. Crymble, G. A. Finegan, H. Gray, W. F. Lane, C. Macauley, T. J. McDonald, C. O'B. Ryan, O. W. J. Wynne.

Examination for the Diploma in Public Health.—J. Casey, F.R.C.P. and S.I., A. Cook, M.D. Univ. Glasg., F.R.C.S. Edin., Capt. O. W. A. Elsner, R.A.M.C., L.R.C.P. and S.I., J. J. A. Gannon, M.B., R.U.I., J. C. Griffiths, M.D. Univ. Lond., A. Leitch, M.B., R.U.I., R. P. McDonnell, L.R.C.P. and S.I., C. F. Watson, M.R.C.S.E., L.R.C.P. Lond., W. P. Warren, L.R.C.P. and S. Edin.

N.B.—The Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland have had under consideration the position of medical students who have taken out some of their examinations in the late Royal University of Ireland, and who may desire to carry on their studies and to take their qualifications under the Conjoint Scheme for Ireland.

The Royal Colleges have decided that candidates for examination under the Conjoint Scheme who have obtained exemption from examination in certain subjects by reason of their having, prior to November 1st, 1909, passed in such subjects at some University or other Licensing body, be excused from payment of half the fees for the Examination or Division of Examination from which they have been exempted.

#### Trinity College, Dublin.

The following have passed the Diploma in Public Health, Michaelmas, 1909:—

Part I.—Joseph W. Houston, Robert B. Anderson.  
Part II.—Samuel B. Smith, Robert B. Anderson, Joseph W. Houston.

OUR energetic contemporary, *The Englishman*, has announced its intention of publishing a series of articles on tuberculosis, and recently, by way of introduction, published a congratulatory letter from Sir Lauder Brunton, together with an excellent full-page portrait of that well-known authority.

## NOTICES TO CORRESPONDENTS, &c.

Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

FOR OWN INSERTION:—Whole Page, 25; Half Page, 23 10s.; Quarter Page, 21 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at 23 10s.; 26 at 23 3s.; 53 insertions at 23, and pro rata for smaller spaces.

Small announcements of Practices, Assistantships, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Dr. Kados (Budapest).—We know of no translation of "The Archives Generales," to which you refer.

### HOSPITAL APPOINTMENTS.

In reply to "Resident's" Inquiry, posts at children's hospitals are much sought after, and are generally announced, when vacant, in the medical journals. One, such as you are seeking, is advertised in our present number, at the Hospital for Sick Children, Great Ormond Street, London. It is the largest and most important children's hospital in the United Kingdom. You will find particulars on reference to our advertising columns.

L. M. S. (Glasgow).—Dr. Mond, whose death was recently announced, was not a medical man, but held the Ph.D. which gave him the prefix by which he was best known. The F.R.S. was awarded him in recognition of his wonderful discoveries in chemistry, gases and allied subjects.

### THE BUDGET AND THE MEDICAL PROFESSION.

WHAT, INDEED!—A member of the medical profession who presided at a political meeting in Nottingham, last week, made the following point in illustrating the biased view which the House of Lords took of the Budget. "Do you think," he asked, "that if it had been a proposal to tax doctors, it would have been referred to the Medical Council? Or if it had been a proposal to tax lawyers would it have been referred to the Law Society?"

ERRATUM.—At the heading of the clinical lecture "on the Prognosis and Etiology of Mitral Incompetence," in our last impression, the author, Sir John F. Broadbent, Bart., was incorrectly described as "Physician to St. Mary's Hospital"; it should have been, Physician to Out-patients at that Institution.

## Meetings of the Societies, Lectures, &c.

### WEDNESDAY, DECEMBER 22ND.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Clinics: Medical Out-patient (Dr. T. R. Whipple); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 p.m.: X-Rays (Dr. H. Pirie).

### THURSDAY, DECEMBER 23RD.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.).—2.30 p.m.: Gynaecological Operations (Dr. A. E. Giles); Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 p.m.: Medical In-patient (Dr. G. P. Chappel).

## Appointments.

ARCHER, T. C. R., M.R.C.S., L.R.C.P.Lond., Clinical Assistant in the Eye Department at St. Thomas's Hospital.

BENTLEY, A. J. M., M.D., C.M. Edin., Lecturer in Tropical Diseases in the University of Manchester.

CHILD, W. N., M.R.C.S., L.R.C.P.Lond., Clinical Assistant in the Surgical Children's Department at St. Thomas's Hospital.

COLDICUTT, CLAUDE E. A., M.D. Edin., Assistant Medical Officer of Health of the County Borough of Leicester.

DELLSCHAFT, M. E., M.R.C.S., L.R.C.P.Lond., Clinical Assistant in the Ear Department at St. Thomas's Hospital.

EARLE, H. G., B.A. Cantab., Joint Lecturer in Biology at Middlesex Hospital Medical School.

FYFFE, E. L., M.B., B.S. Lond., M.R.C.S., L.R.C.P.Lond., Obstetric House Physician at St. Thomas's Hospital.

GRAHAM-JONES, J. L., M.R.C.S., L.R.C.P.Lond., Junior Obstetric House Physician at St. Thomas's Hospital.

HOPWOOD, J. S., M.R.C.S., L.R.C.P.Lond., Clinical Assistant in the Ear Department at St. Thomas's Hospital.

HUMPHREYS, H. E., M.R.C.S., L.R.C.P.Lond., Clinical Assistant in the Skin Department at St. Thomas's Hospital.

HUNTER, G. F., M.B. Aberd., Junior Assistant Physician to the Ayr District Asylum.

MCDONAGH, M.R.C.S., L.R.C.P.Lond., Medical Officer for the No. 2 District of Southampton.

MARKLOVE, J. C., M.R.C.S., L.R.C.P.Lond., Clinical Assistant in the Skin Department at St. Thomas's Hospital.

MATBURY, B. C., M.R.C.S., L.R.C.P.Lond., Clinical Assistant in the Throat Department at St. Thomas's Hospital.

MEAKIN, L., M.R.C.S., L.R.C.P.Lond., Clinical Assistant in the X-Ray Department at St. Thomas's Hospital.

MORCOM, A. F., M.R.C.S., L.R.C.P.Lond., Clinical Assistant in the Throat Department at St. Thomas's Hospital.

PARKINSON, W. R., M.R.C.S., L.R.C.P.Lond., Clinical Assistant in the Surgical Children's Department at St. Thomas's Hospital.

PRIDHAM, F. C., M.R.C.S., L.R.C.P.Lond., Clinical Assistant in the Medical Children's Department at St. Thomas's Hospital.

QUINN, A. E., M.B., Ch.B. Vict., Senior Assistant Resident Medical Officer at the Whitechapel Union Infirmary.

ROUTE, L. M., M.R.C.S., L.R.C.P.Lond., Clinical Assistant in the Medical Children's Department at St. Thomas's Hospital.

ROWNTREE, CECIL, M.B., B.S. Lond., F.R.C.S. Eng., Assistant Surgeon to the Cancer Hospital.

WINK, C. S., M.R.C.S., L.R.C.P.Lond., Clinical Assistant in the Mental Department at St. Thomas's Hospital.

## Vacancies.

Somerset County Council.—Assistant School Medical Officer. Salary £2.0 per annum, with necessary travelling and out-of-pocket expenses. Applications to the County Education Secretary, Weston-super-Mare.

Edmonton Union.—Resident Medical Superintendent. Salary £400 per annum, with unfurnished apartments, fire, light, and water, but no rations, furniture or service. Applications to F. Shelton, Solicitor and Clerk, "The Grange," White Hart Lane, Tottenham.

Gardians of the Wandsworth Union.—Assistant Medical Officer at the Home for Aged and Infirm, Church Lane, Tooting. Salary £130 per annum, with apartments, board, lodging and washing. Applications to F. W. Piper, Clerk, Union Offices, St. John's Hill, Wandsworth, S.W.

County Borough of Great Yarmouth.—Medical Officer of Health. Salary £400 per annum. Applications to W. Edgar Stephens, Town Clerk, Town Clerk's Office, Town Hall, Great Yarmouth.

Wye House Asylum, Buxton.—Assistant Medical Officer. Salary £120 per annum, all found. Applications to the Medical Superintendent.

Leeds Public Dispensary.—Junior Resident Medical Officer. Salary £100 per annum with board and lodging. Applications to the Secretary of the Faculty, Public Dispensary, North Street, Leeds.

Free Eye Hospital, Southampton.—House Surgeon. Salary £18 a year, with board and residence. Applications to Major I. W. Heathcote, Secretary.

West Herts Hospital, Hemel Hempstead, Herts.—House Surgeon. Salary £100 per annum, with rooms, board and washing. Applications to Robt. L. Butterfield, Assistant Secretary at the Hospital.

Manchester Children's Hospital (Out-patients' Department), Garside Street, Manchester.—Assistant Medical Officer. Salary £100 per annum. Applications to H. J. Easton, Secretary.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—House Surgeon. Applications to the Secretary. Salary £30 for six months, washing allowance £2 10s., with board and residence in the Hospital. (See advt.)

## Marriages.

WHITTINGTON—RIDSDALE.—On Dec. 15th, at St. Mary Abbots, Kensington, Richard Whittington, M.A., M.D., of Silwood Place, Brighton, to Lilian Esther Ridsdale, younger daughter of the late E. L. J. Ridsdale, of Hyde Park Gate, and Rottingdean.

ST. JOHN—TWIGG.—On Dec. 18th, at St. Peter's Cranley Gardens, Winston Street, Andrew St. John, M.R.C.S., L.R.C.P., of Derwent House, Derby, eldest son of R. F. St. Andrew St. John, Esq., late 60th Rifles and Burma Commission, to Violet Julia Louisa, second daughter of Henderson James Twigg, Esq., of Petane Grange, Petane, Hawks Bay, New Zealand.

## Deaths.

KEMBLE.—On Dec. 11th, at Willoughby, Rugby, Mary Elizabeth wife of Arthur Charles Kemble, L.R.C.P., L.R.C.S. Ed., aged 46.

MAYNARD.—On Dec. 15th, at 4 Sutherland Avenue, Maida Vale, London, W., James Payne Maynard, M.B., M.Ch., the second son of the late Wm. P. Maynard, of Cork, aged 44 years.

PENDLEBURY.—On Dec. 13th, at Underwood, Grange-over-Sands, Marian, daughter of the late John Pendlebury, M.D., F.O.P.S. Cantab., of Manchester.

ROSCOE.—On Dec. 17th, at Stoke-on-Trent, Henry Roscoe, M.R.C.S. Eng., L.R.C.P.Lond., House Governor of the North Staffordshire Infirmary.

No. 26.

## NOTES AND COMMENTS.

### No Small-pox Patients.

At a recent meeting of the South Staffordshire Joint Small-pox Hospital Board, at Wolverhampton, the question of using a small-pox hospital for the reception of phthisis patients was discussed. It appears that the hospital was built some years ago, but there had been no small-pox cases to put in it. The Medical Officer of Health, Dr. Reid, suggested it should be used for consumptives, and the local authority thereupon communicated with the Local Government Board. This raised the usual circumlocution storm. The official reply was to the following effect:—It did not appear to the Local Government Board, having regard to the terms of the South Staffordshire Joint Small-pox Hospital Order, 1903, that the Joint Small-pox Hospital Board could themselves undertake the treatment of cases of phthisis in their hospital. At the same time, the principle to utilise the hospital thus when the accommodation was not required for cases of small-pox was not one to which the Local Government Board would raise objection on medical grounds, assuming that the hospital were efficiently disinfected between its use for the two diseases, and provided that the consumptive patients could at once be removed in the event of cases of small-pox being notified. If it were proposed to let the small-pox hospital to a Hospital Committee of the Staffordshire County Council for the use of consumptive patients on the conditions indicated, and a Provisional Order were needed to enable the proposal to be carried into effect, the Board would be willing to consider an application for such an order.

### Further L.G.B. Views.

SUBSEQUENTLY, the Clerk of the local authority interviewed the Assistant-Secretary of the Local Government Board, when the following suggestions were made:—In the first place, the County Council should pass a resolution authorising the addition of phthisis to the list of infectious diseases. They should then appoint a committee under the Isolation Hospitals Act, which should include members of the Wolverhampton Council. The County Council should then agree with the Small-pox Hospital Board for the temporary use of the hospital, it being understood that if an epidemic of small-pox occurred the phthisis cases should be instantly removed. As Wolverhampton was a county borough and outside the Isolation Hospitals Act, it was suggested that the Wolverhampton Corporation should agree with the County Committee for so many beds or patients from Wolverhampton. By those measures the Assistant-Secretary thought the matter might be carried out, but he was very much averse from anything like a permanent arrangement, as the

Board anticipated, having regard to the long period which had elapsed since the last small-pox epidemic, it was safe to predict that sooner or later another would occur.

### Insurmountable Difficulties.

No wonder that the Chairman, in the brief discussion that ensued, expressed his opinion that the difficulties in the way of adopting the scheme were insurmountable. It is, of course, right that the Local Government Board should insist on every step in public health administration being taken in a legal and orderly fashion. At the same time, we cannot help regarding it as a little unfortunate that a local authority, bent on taking what is clearly a common-sense step in the direction of economy, should find so many obstacles in the plan. One would have thought, for instance, that any possible epidemic of small-pox might be provided for by the erection of a few galvanised iron huts. One happy feature of this otherwise uninspiring incident is the absence of patients for the small-pox hospital. Would that Jenner might return to the earth for a brief space of time and view a huge modern hospital built for small-pox patients, of whom not one had been known in the district for years past! Then we would have him look in for half-an-hour or so at an anti-vivisectionist meeting before flitting back to the region of spirits. (Anti-vivisectionists are at liberty to the copyright of this and the two preceding paragraphs.—ED., M. P. AND C.)

### Viavi Methods.

THE ways of the secret remedy vendors are multifarious, and display a business ingenuity and "pushfulness" that are simply astonishing. Some few weeks ago, a correspondent drew our attention to the fact that the Viavi remedies were advertised in the tram-cars of Hastings and St. Leonards, one of the most famous of our health resorts. At the same time, he pointed out the scathing revelations of the Viavi methods and remedies given in the American Medical Association's propaganda for reform in proprietary medicines. The methods adopted by the Viavi Company have been exposed many years ago in the United Kingdom, but there must be a good deal of money in the thing, for it is still being exploited in this country. *Truth*, which has always kept a watchful eye upon the proceedings of the Viavi Company, published on December 15th a further disclosure. It is stated in that journal that it was suggested to a lady canvasser who had not made a pecuniary success of her post, that she should invest £50 or £100, in which case she would be appointed to one of the best districts and sent to interview likely customers. This

method of unloading shares in a concern that, under the glare of recent exposures, are not likely to rise in value, is one not unfamiliar to "smart" commercialism. It certainly should place a heavy discount upon the blandishments of ladies who are worried to attend Viavi lectures.

**Nationalisation of Medicine.** THE proposal to nationalise medicine was raised some days ago at Plymouth, when Mr. R. Jaques gave a lecture at the Athenæum on "The Nationalisation of Medical Service." As the lecturer pointed out, there is a considerable amount of overlapping in the various medical services of the country, and his suggestion that Poor-law medical work should be merged in public health organisation doubtless deserves serious consideration, as even now the two appointments concerned are often held by the same individual. His further suggestion that the public health service should be national and not municipal, is already recognised in part. The county medical officers of health can no longer be removed from their posts without the consent of the Local Government Board, and to that extent there is central control. Mr. Jaques' final suggestion that all hospitals should be nationalised and the medical staffs paid, may, we think, require careful consideration. Freedom is the breath of life to science, and outside authority, be it ever so sympathetic, may perhaps tend to limitations which might lessen the independence which is so characteristic of our profession. Such a loss, while pernicious to physic, would be detrimental in the long run to the public also. Hospital appointments have always carried their own reward in the past, and will continue to do so in the future, especially as the outlook of specialism appears ever to be widening.

**Research Defence.** IN these days of partisanship it is refreshing to hear a man like Lord Cromer speak upon medical research. Among the useful offices filled by this great pro-consul is that of President of the Research Defence Society. On the 13th of this month he presided at a meeting held in the Royal Pavilion, Brighton, and dealt with the rights of all parties concerned, that is to say, the public, the anti-vivisectionists and the vivisectionists; at the same time he made it clear that, in his opinion, control by the authorities was justifiable to the extent of preventing unnecessary pain. These remarks coincide with our own expressed last week on the point. We trust those good folk who would not permit the killing of a cat to save the life of a bishop will give to Lord Cromer the considerate hearing they might deny to anything hailing from medical quarters. Sir A. Conan Doyle, who supported Lord Cromer on the above-mentioned occasion, claimed that animals benefit in a great measure from the investigations made on their kind. He cited the vast number of cattle now saved from a painful death by anthrax, rabies, rinderpest, and other diseases. Apart from the question of cure, he referred to the decrease of epidemics, due to the early diagnosis of disease. The more local branches of the Research Defence Society the better, for there can be no question that meetings like the one at Brighton will in time remove the dust raised around scientific research by anti-vivisectionists.

**Grouse Disease.** THE communication made by Dr. H. B. Fanshaw to the Zoological Society at its last scientific meeting forms a kind of interim report of the Commission on Grouse Disease, which was

appointed some time ago, and of which he is the protozoologist. Dr. Fanshaw's research seems to demonstrate the fact that the enteritis and diarrhoea which affect grouse chicks during the first month or six weeks of their life are due to a sporozoan parasite, *Coccidium avium*. The spores gather in the *cæcum*, pass out in the droppings and are swallowed by other chicks. The spores first exist in a cyst, which is dissolved by the pancreatic juice. Each liberated spore contains eight animalcules. Maggots of the dung fly also swallow the cysts, and passing them unaltered help to spread the disease. The *cæca* of adult grouse often contain large numbers of nematoid worms, and the cysts were first taken for their eggs; but some experiments by Dr. Leiper having established the fact that they were not worm eggs Dr. Fanshaw was able to trace their true pedigree. Dr. Fanshaw has been able to transmit grouse disease to fowl chicks and young pigeons. It is to be hoped that the Commission at the end of its labours may be able to formulate measures for the prevention of the disease, the ætiology of which seems now almost completely made out.

## LEADING ARTICLES.

### EXPERIMENTAL RESEARCH.

THAT the nature of mankind is in its essence conservative is shown by the way in which it clings to ancient habits, customs and details of its surroundings. Amid a wealth of illustrations, it may be pointed out that the common wood-chopper of to-day differs little in form from a polished flint axe of a prehistoric stone age; the common brown jug of the English cottager might have been dug out of the site of some Romano-British camp; the railway compartment carriage retains the stamp of the stage-coach of former days; and so on *ad infinitum*. The general truth appears to be that change in established and familiar forms and usages and the introduction of fresh ideas are slow and gradual. From this point of view it may be conceived that, as a whole, society has not yet grown accustomed to the use of the lower animals for the purposes of experimental research. There can be little doubt that the bitterness of many anti-vivisectionists is due to an imperfect recognition of the facts of the case. The more that one knows about the methods and results of experimental research, the more one is led to the inevitable conclusion that it is one of the unavoidable evils necessarily inflicted by man upon the lower animal for his self-protection and self-preservation, just as he eats their flesh and uses their hides, hair and bones for processes directly and indirectly connected with his own well-being. So far as the education of the public is concerned, the Research Defence Society, founded in 1908 by Mr. Stephen Paget, has done, and continues to do, most valuable work. At the recent opening of a Liverpool branch of the organisation, the pith of the matter was excellently put forward by Lieut.-Colonel J. Pilkington, F.S.A. The parent Society, he explained, was started by a number of eminent scientists and laymen, who felt it to be an absolute necessity in the interests of suffering humanity that an association should be formed of persons willing to aid in thwarting any undue and antagonistic efforts of the anti-vivisectionists.

tionists. That proposition goes to the root of the matter, for the medical profession has always readily fallen in with the demand for reasonable control over experimentation in order to vindicate their own position, as well as to reassure the public. With that end in view, experiments are performed only by licensed individuals, under Government control, and in accordance with an Act of Parliament, which, owing to some extraordinary obliquity of mental vision, the anti-vivisectionists wish to have abolished. The Society has made it a chief feature to collect and publish accurate information as to what is actually done in scientific circles, where the lower animals are used for purposes of experimental research; and they have put a large quantity of literature in circulation. In that effort they have simply endeavoured to act upon the opinion of many candid and competent judges, who hold that the continuance of such experiments is of the highest importance, not only to the present general welfare of mankind, but also to the future physical well-being of humanity. It should be borne in mind that research experiments are necessary, not only in combating disease, but also in the standardisation of medicines, in the control of our milk supplies, in the diagnosis of many infectious maladies, and in the investigation of cancer, sleeping sickness, Malta fever, and many other deadly diseases. Reducing the matter to simple terms, would be the anti-vivisectionist deliberately value the lives of half-a-dozen guinea pigs above the possible infection of half-a-dozen children by tuberculosis in milk? In the parlance of the public orator, we pause for a reply. Meanwhile, on turning to the latest available official figures, we find that rather over 96 per cent. of the "experiments" reported were simple inoculations or hypodermic injections, many of them practically painless in character; and, further, that more than half of the 96 per cent. were made in the study of cancer. The remaining half were largely examinations conducted by the Home Office and by public bodies to benefit public health. The serious operations were only  $3\frac{1}{2}$  per cent. of the whole, and in these anaesthesia was, of course, an indisputable legal condition. Colonel Pilkington made the sensible remark that experimental work was likely to be misunderstood so long as the Anti-Vivisection Society continued to spread misleading information, basing its indictments on what was alleged to take place on the Continent or in the United States, and by quoting what had happened in the United Kingdom prior to the passing of the Act which regulated and confined operations. Finally, he alluded to the significant fact that on the list of the Vice-Presidents of the Research Defence Society were eighty-seven of the leading clergy of the country, largely archbishops, bishops and deans. The "significance" of the movement, from his point of view, arose from the reflection that thinking men from that class of society would not lend their aid to the movement unless they felt satisfied that operations upon the lower animals were a necessity, and could not, therefore, be displeasing to the Almighty. And so, we are happy to think, will one day think the overwhelming majority of our cultured fellow countrymen.

### THE GREAT FATAL FIRE IN LONDON.

THE occurrence of a fatal fire in some large stores at Clapham Junction raises a number of pertinent questions in the interests of the public safety. The fire broke out in the afternoon, when the shops were not at their busiest, but, nevertheless, a number of lives were lost—it is estimated from ten to twenty—but the precise number may never be ascertained. The fire originated in one of the shop windows, and although gallant attempts were made to extinguish the flames, they spread rapidly until they involved the whole of a huge block of buildings. Now, there is a plain moral to this tragic story. Had the buildings been fireproof, or, to use a more accurate term, fire-resisting, the spread of the conflagration would have been proportionately slow, so that time would have elapsed for the fire-extinguishing brigades to have come to the rescue. In that way a lamentable loss of life and an enormous damage to property would probably have been averted. Surely an event of this kind may be described as, humanly speaking, avoidable, at any rate, as regards its more serious results, by the application of scientific knowledge. Why should not a huge modern building of this kind be made with fireproof floors? A provision of that kind is calculated to limit and control and retard the spread of a fire, if not to prevent it altogether. The Clapham Junction outbreak took place in the daytime, a far more favourable time for the chances of extinction than had it occurred during the night. Of recent years the London County Council has effected great improvements in the safety of factories and workshops by the provision of adequate exits and emergency stairs. There are many unsafe buildings where workpeople are employed which technically escape the operation of the Factories and Workshops Acts. Then, again, it is impossible to enforce structural precautions under the Building or other Acts in many old buildings, in spite of the fact that they may be so constructed as to form veritable death-traps in case of conflagration. An instance of this kind occurred in the year 1902 in the case of a fire in a rubber warehouse in Queen Victoria Street, in the City of London, where a number of workpeople lost their lives. It would be difficult to imagine a more fatal plan of construction than that which, on the outbreak of the fire, speedily cut off several floors full of employees from the ordinary and circuitous route of exit. The exact facts and circumstances of the Clapham Junction fire remain to be ascertained. Whatever the result of those inquiries may be, the question we have raised will remain unaffected. Why should not these huge industrial or industrial and commercial blocks be constructed of fire-resisting materials? The additional cost would not be prohibitive in extent, whereas, on the other hand, the gain to the security of all concerned would be almost incalculable. In the attempt to obtain greater security for citizens against fire, the London County Council have often had to face strenuous opposition on the part of property owners. It is to be hoped that in view of the serious fatal fires that have occurred within their jurisdiction, they will be enabled to present the legislature with an overwhelming case

for the necessity of amended and consolidated and extended legislation with regard to industrial and commercial buildings, or, for that matter, of all large buildings, public or private, within the metropolis.

### CURRENT TOPICS.

#### Scarlet Fever and Pasteurised Milk.

A STRIKING testimony to the value of pasteurisation of milk in the prevention of scarlet fever was given in a recent report issued by the Public Health Committee of the Lambeth Borough Council. An epidemic of the disease in question prevailed at Kingston, Wimbledon, Croydon and surrounding districts, including several in Westminster and south of the Thames. "In regard to the Lambeth outbreak," the report says, "it appears to have been limited to a public institution. The medical officer informs us that, in his opinion, the outbreak connected with infected milk would have been much more widely extended, had it not been for the fact that all milk used by the institution was pasteurised before use, except such milk as was to be used for cooking purposes." It appears that the inmates and patients at the institution escaped infection, although there were many susceptible persons—children, invalids, etc.—who partook of the milk at the time. It was the members of the nursing staff alone who were infected. The nursing staff occupies the nurses' home away from the rest of the institution. Inquiry showed that the milk used by the nursing staff was not pasteurised, although this fact was unknown to the management of the institution at the time, and that had it been so, even these cases of scarlet fever would doubtless have been prevented. The facts point to the value of all milk being pasteurised or sterilised before being consumed, milk being specially liable to infection both from human and animal sources. It would be difficult to devise a more conclusive experiment as to the transmissibility of scarlet fever by a specific virus conveyed in milk and destroyed by the process of pasteurisation.

#### Change of Air.

PERHAPS one of the oldest of all medical prescriptions is that known to us as "change of air." When a patient has passed through a sharp illness, who can doubt that his convalescence may often be shortened or rendered more complete by a visit to the seaside or to some wholesome inland resort? What else has made the reputation of so many spas and watering-places of all kinds and descriptions? It is, of course, the fashion to say that the change of air is only part of a "cure" at a health resort, and that other things equally potent are regular living and exercise, early hours, plain fare, and the absence of social and business worries. In spite of all that may be said on that score, the fact remains that there is something in the substituted air itself which seems to satisfy some demand of the debilitated system. When we come to know more accurately the composition of air and its radio-active and other less obvious activities, it is possible that the key may be found in the beliefs that in us lie as to the virtues attached to

"change of air." By some irony of fate, it is precisely the one prescription most difficult for the medical practitioner to apply to his own case, however supersaturated he may be with the air of one particular locality.

#### Women as House Surgeons.

SOME weeks ago we stated the fact that the Board of Management of the Manchester Royal Infirmary had carried a resolution against the admission of women to the post of house-surgeon. The resolution declared that in a general hospital the services of medical women are not, upon the whole, as valuable as those of men, and as the adoption of such appointments in their institution would entail building operations, and other causes of great expense, the Board would not be justified in making an experimental change not of advantage to the Infirmary. This resolution has created great dissatisfaction among the registered medical women of the district, and, aided by their own Association, several kindred organisations, and a considerable body of influential citizens, they have formed a committee with the object of obtaining a reversal of the Board's decision. The Committee urge that to deny to all women medical students in Manchester, the opportunity of holding resident posts in the Infirmary will tend to discourage women who desire to enter the profession, and will make the Manchester Medical School suffer by driving women to other places where more liberal views prevail. They insist that wider issues are also involved affecting the interests of the whole community. Without pretending to pass judgment on the question of expense, which the Board alleges as a chief ground for their adverse decision, or now deciding the question of the employment of medical women in male wards, it seems evident that, under normal conditions in a great hospital attached to a great medical school where women are educated, an opportunity ought to be afforded to all qualified students, regardless of sex, of obtaining, so far as possible, that experience in the position of house-surgeon which forms so valuable a termination to the student's career. In a hospital containing some hundreds of beds in the female wards, enough work for women house-surgeons could surely be found; and if, as it seems, the problem in Manchester be really, in the main, one of expense, it need not be doubted that her wealthy citizens will soon bring about a satisfactory solution.

#### Chinese Pork.

THE absolute necessity of a rigid control over the importation of Chinese pork has been amply demonstrated by a recent report upon the subject by the Medical Officer of Health for the City of London. Out of 2,131 carcasses dealt with, no less than 214 were condemned. It is somewhat of a shock to learn that 10 per cent. of Chinese pigs imported into this country are in a condition capable of spreading disease among consumers. A further danger has been revealed by the Local Government Board, which has issued information that consignments of pigs' stomachs have been sent from Hamburg packed in salt, and that some of these stomachs show signs of gastritis. The fact that they are used for sausage-skins suggests

a further lurid danger. Indeed, in our opinion, the whole matter of sausage-skins demands legislative treatment. The use of the intestinal canal of various animals for packing sausages opens up an obvious danger of infectivity by bowel organisms, especially when the sausages are eaten uncooked. Considering the revelations that are constantly being made about sausages, it is a wonder that their consumption has not dwindled long since to vanishing-point, as in the case of the incriminated oyster.

#### Scouting for Girls.

FOR some time past the organisation known as "Boy Scouts" has been gradually growing in popularity, and for this there are sound reasons. Whether we approve of the military spirit fostered by the movement or not, no one can deny that the open air employment, the observation of natural features, and the wholesome exercise, involved in scouting have a physical and educational value not to be lightly esteemed. It will be a surprise to many, however, to find that some of those concerned in the "Boy Scouts" movement, not content with teaching boys scouting duties, are also taking girls in hand for the same work, or play. According to a correspondent of the *Spectator*, girls of all ages from twelve to sixteen are sent on scouting parties with boys of the same age, and without any efficient supervision. They return home late at night after a long afternoon in the country, hot, tired, and in an excited frame of mind. It is not necessary to dwell on the physical and moral evils likely to spring from such conditions as these, or to emphasise the folly of those who encourage or permit them. The idea may perhaps have been suggested by the co-education movement which, as explained frequently in these columns, has achieved great success in highly organised schools under expert direction—a movement in no way justifying experiment such as that now referred to. We can hardly believe that General Baden-Powell and the other responsible heads of the "Boy Scouts" movement are to answer for the "Girl Scouts," and we are sure that now that the matter has been brought to their notice, their influence will be sufficient to put a stop to a movement even more dangerous than it is silly.

#### As Others See Us.

THE hospitality of one of our professional contemporaries has given the opportunity to Mrs. Hodgkinson, editor of the *British Health Review*, to express her frank opinions of our profession. Her criticisms are, on the whole, framed in courteous terms, and are deserving of some attention, in that they represent the attitude of the ignorant and somewhat careless man-in-the-street, when he wants to have a grumble. The intention so obviously is to grumble rather than to suggest reforms, that we come away less instructed than we had hoped to be. In so far as Mrs. Hodgkinson's criticisms are well founded, she voices what we all know, only too well. She deplores, as we all do, the treatment of symptoms, but what she does not see is, that in some cases we can find nothing but symptoms, and the patient, very naturally, expects to have them treated. She objects to the specialisation of medical work, and in turn demands much more rigorous consulting-room methods than at present:—"These (so to speak) drawing-room methods should be discarded in favour of a really searching examination, including blood counts, test meals, and many other means." But even the consultant cannot be an all-round specialist, for there is a limit to the work a man can do well. On

the question of fees, Mrs. Hodgkinson is annoyed equally with the operating surgeon, who wants his fee at once, and with the general practitioner who sends in his bill half-yearly. When she complains that the fee for a surgical operation "in no sense represents its actual, though it may its market, value," we do not quite understand, unless, indeed, she is stating the platitude that health is invaluable. We cannot follow Mrs. Hodgkinson in all her criticisms, but we would point out to her that her most offensive suggestion, to the effect that it is to the interest of medical men to prevent good health, is met by her own admission of the excellence of the work done by the medical officer of health.

### PERSONAL.

THE QUEEN has sent chocolates to Sir William Treloar for the inmates of the Cripples' Home at Alton.

PRINCE ALEXANDER OF TECK has sent a donation to the funds of the Margaret Street Hospital for Consumption.

MR. WILLIAM PEARSON has been appointed Assistant Surgeon to the Adelaide Hospital, Dublin.

MR. HENRY PHIPPS, the steel merchant, has given the sum of £100,000 to the University of Pennsylvania for medical and surgical research purposes.

THE St. John's Hospital for Diseases of the Skin has received a donation of £500 for the naming of a ward to be called the "Annie Zunz" ward.

SIR WM. THORNLEY STOKER, M.D., has been appointed Inspector of Schools of Anatomy in Ireland, in the room of the late Sir Wm. Thomson, C.B.

AT the Clerkenwell Police Court, Achilli Mompaldo, a registered medical practitioner of the Italian quarter, was fined 30s. for failing to notify a case of puerperal fever.

DR. THOMAS ADRIAN GREENE, Resident Medical Superintendent of Carlow District Lunatic Asylum, was sworn a Justice of the Peace for the County of Carlow.

THE Paris Pasteur Institute has had its expenses increased by £400 a year by reason of the increased duty put on alcohol by M. Caillaux when Minister of Finance.

DR. FRANCIS WARD stated, on December 22nd, at the Royal Photographic Society, how fish can be successfully photographed, if first put under the influence of chloroform.

THE following have been appointed Justices of the Peace:—Dr. George Black, of Tomintoul; Dr. William R. Duguid, jun., of Buckie; Dr. John S. Findlay, of Glenlivet; and Dr. Alfred D. Vardon, of Gardinstown.

DR. J. DUNCAN LOVE, who is leaving Newcastle-on-Tyne after fourteen years' work to take up practice at Monkseaton, was presented with a silver tea-tray and caddie by grateful patients on December 21st. Sir William Angus, J.P., made the presentation.

THE London committee of management for the public health section of the Japan-British Exhibition at the White City for 1910 includes Professor H. E. Kenwood and Colonel J. Lane Nottter, and sub-committees are to be formed in many of the great industrial and mercantile centres in Great Britain and Ireland.

OWING to the Christmas holidays, our Irish SUPPLEMENT will not appear this week.

# A CLINICAL LECTURE ON THE TREATMENT OF CONGENITAL TALIPES EQUINO- VARUS IN INFANTS. (a)

By WALTER C. STEVENSON, M.D., B.Ch.,

Surgeon to the Orthopædic Hospital of Ireland, Dublin.

BEFORE entering on the details of the treatment of congenital talipes equino-varus, I think it would be an advantage to let you know the *rationale* of the routine which Mr. Swan has adopted and carried out, with the most satisfactory results, at the Orthopædic Hospital for the last thirty years.

The treatment is essentially a gradual rectification of the deformity until over-correction is well established. During its progress one principle must be constantly borne in mind, namely, that once the treatment is begun, the foot should never be allowed for one instant to go back to its original shape, or even to a less-corrected position. Treatment should be continued until this tendency to relapse has been completely overcome.

Briefly, the conditions we find in the foot, or more commonly in the feet, of a child born with this deformity are:—(1) A *Varus*, or bending inwards, and a supination of the anterior segment of the foot, taking place to a large extent at the medio-tarsal joint; and (2), an *Equinus*, which mostly affects the ankle-joint. The *Varus* deformity is more tedious to cure, and it is found by experience much easier to rectify this before any attention is paid to the *Equinus*. The tense *tendo Achillis* gives great stability to the foot during the application of the correcting forces. When the *Varus* is cured it is a more simple matter to overcome the *Equinus*.

There are two procedures employed in each deformity, the tenotomy of resisting tendons, and the manipulation of the foot. The major part of the treatment consists in the manipulation, which, under ordinary circumstances, in this hospital is carried out by the sister or a trained nurse. Nevertheless, by dividing certain tendons, the time required to obtain the result aimed at is shortened, and the likelihood of recurrence minimised. The sequence of events is, therefore, as follows:—(1) Tenotomy of the posterior and anterior tibial tendons; (2) manipulation of the foot until the *Varus* condition is completely corrected, or, rather, over-corrected; (3) tenotomy of the *tendo Achillis*; (4) correction of the *Equinus* by manipulation and the night-shoe; (5) teaching the patient to walk properly.

It is the practice here to commence the treatment as early as possible; preferably, in a healthy child, when it is a fortnight old. Anyone handling an infant's foot will at once appreciate how easily it can be twisted into any shape, and, at the same time, how quickly it will spring back to its original position. All the tissues are much more pliant than in an older subject. If one considers an X-ray photograph of such a foot, it becomes strikingly evident that there is little bony matter in the tarsus, which consists for the most part of cartilage; the central portion of the os calcis, and to a less extent the astragalus, are represented by small globular nodules of bone, and the cuboid is just beginning to ossify. The centres for the external, middle and internal cuneiforms appear in

that order during the first, second and third years, and the scaphoid still later. From this point of view, the advantages of early treatment are obvious. Resection of bone is out of the question, as there is little or no bone to resect. In the course of a few weeks the foot can be moulded so as to present a normal appearance. When the infant grows older he will learn to use his feet as does an ordinary child. This result is accomplished without sacrifice of the bony architecture or shortening of the foot. Cure is also effected in a much shorter time in early cases. The little patient is caused less inconvenience and discomfort than the older child, and, at least, is spared the terrors of anticipation each time the foot is about to be manipulated.

Nearly all the city infants presented here are treated in our dispensary as out-patients. This arrangement is not so satisfactory with older children, as they require constant watching to prevent them from disturbing their bandages. If the case is taken in hand soon after the mother can get about, and while she is still unfamiliar with and distressed on account of the abnormality of her offspring, she is more likely to be regular in her attendance, and to be encouraged, rather, by the comparatively rapid improvement which she sees from day to day. By watching the treatment, most mothers, with a little training, learn to manipulate the feet themselves, so that they are able to take an intelligent interest in the case. They may usually be entrusted with such subsequent care of the feet as will ensure the correct position being maintained until the child is well able to walk.

I now propose to discuss some of the details of treatment. With the usual aseptic precautions, the posterior and anterior tibial tendons of one or both feet are divided at one sitting with a fine, sharp-pointed tenotome. The nurse can keep the limb absolutely quiet by pressing the knee backwards with the tips of the fingers placed on the quadriceps extensor, just above the patella. To cut the posterior tibial tendon, the leg, lying on its outer side, is held with one hand placed beneath it. The tenotome is entered at right-angles to the middle of the inner surface of the leg, and the blade, as it is passed in, is parallel to and just grazes the inner border of the tibia. If introduced properly, the tenotome will stand by itself, being held against the posterior surface of the tibia by the tendon. The edge of the blade is now turned towards the tendon, which is stretched and severed over it by everting the foot. Similarly, the anterior tibial tendon is dealt with by passing the tenotome directly towards the bone through the anterior annular ligament, immediately external to the tendon. This is then picked up by passing the blade horizontally inward under it, and cut as before. A pad of a double fold of sterilised lint about half an inch square is placed on each puncture, and held in position by strapping. Then a flannel bandage is applied to the foot and leg. Beginning at the inner margin of the foot, it is

(a) Delivered to the Post-Graduate Class of the Royal College of Surgeons of Ireland at the Orthopædic Hospital, on October 6th, 1909.

brought beneath the sole and across the dorsum, because its application in this direction is an important adjunct in maintaining the correct position. A malleable splint made of hoop-iron, padded with tow and covered with calico, is so bent that, when it is bandaged to the inner side of the foot and leg, it will correct the *Varus* to a slight extent.

The bandage and splint are not disturbed for four or five days. These and the dressing are then removed, and the foot gently manipulated, after which the bandage and splint are re-applied. As the foot improves, the splint is placed on the outer side of the limb, and is bent gradually until the foot can be retained against it in the *Valgus* position without undue strain.

The *technique* of manipulating the foot to the best advantage is easily acquired if a few practical points are attended to. Of these, the most important is to keep the ankle well fixed, so that the correcting forces may not be dissipated in moving the ankle, and also in unnecessarily stretching the ligaments round that joint. The leg should be kept steady by an assistant, as before described. The anterior part of the foot should be brought by a circular motion to a position of *Valgus* and pronation, so that the sole looks outwards and forwards instead of inwards and backwards. If the right foot is being manipulated the right hand is placed behind the heel, and grasps the malleoli, the os calcis and the astragalus. The thumb is along the tibia and points to the knee. The fingers are along the fibula, and are more or less parallel to one another. The palm of the left hand is against the sole, the thumb on the dorsum, and the web of the thumb presses against the inner margin of the foot behind the head of the first metatarsal bone. This arrangement of the hands gives great power in untwisting the foot. When the untwisting movement has been performed several times, the right hand is slipped down somewhat to the inner side of the foot to keep up the *Valgus* position, while the head of each metatarsal bone is pulled in an outward direction with the fingers of the left hand. This tends to spread out the foot and to stretch the ligaments at the bases of the metatarsal bones.

Manipulation is continued once or twice daily until the *Varus* is completely corrected. This may take from two weeks to two months or more, according to the age of the child, and the regularity and the efficiency of the manipulation and bandaging. Once the *Varus* is completely corrected the foot will remain in the *Valgus* condition when left to itself. Also, when manipulated into the *Valgus* position the skin on the inner side of the foot will not blanch, showing that it has been sufficiently stretched.

The *tendo Achillis* may be divided subcutaneously from either side, but it should be cut well above the insertion. A pad is applied as before, and the splint, slightly bent opposite the ankle, is placed along the anterior aspect of the limb; there is little danger of producing flail foot, an accident which may very easily happen in paralytic cases, as the shortened posterior ligament of the ankle will not permit of immediate correction of the *Equinus*.

After four or five days the foot is again manipulated daily, but now, in order to bring down the heel, the movement of dorsi-flexion of the foot is superadded to those already described. Two or three days later, the splint, which has been in use from the commencement of the treatment to maintain the foot constantly in proper position, is discarded for Swan's night-shoe. This apparatus is simple, inexpensive, and, when properly applied, most efficient. It serves to complete the cure and

to prevent the recurrence of the deformity. It consists of a U-shaped metal trough, extending from the heel two-thirds of the way up the back of the leg, with a flat, immovable foot-piece welded on at right-angles to it. At the lower end of the leg-piece there is a shaped gap, through which the back of the heel can project comfortably. The whole shoe is covered with chamois leather. On the convex surface of the trough, to the inner side of this opening, a strap is fixed near the foot-piece. Its buckle is in a corresponding position on the outer side of the heel-gap. The foot is bandaged as before, and placed in the night-shoe, with its whole plantar surface in apposition with the foot-piece, the back of the heel projecting a little behind. The strap is brought forward through the gap, between the inner side of the ankle and the trough, across the front of the ankle, back between the outer side of the ankle and the trough, through the gap, and buckled off on the outer side. This strap holds the ankle firmly in position. For the first week or so, until the *Equinus* is to some extent corrected by manipulation, it is not advisable that too much pressure be exerted in attempting to keep the sole flat against the foot-piece. There is another strap round the leg to hold the trough in position. The night-shoe is then bandaged on from above downwards. Any degree of eversion of the anterior part of the foot may be obtained by passing the bandage downwards across the inner side of the foot, outwards beneath the sole, and by pulling it round the outer edge of the foot-piece, the ankle being fixed as before described. For two or more months the night-shoe should be worn constantly, except when the foot is being manipulated; subsequently it is put on only at night-time, and is kept in use till the child begins to walk.

The child with club-foot should not be encouraged to crawl, as the pressure on the dorsum of the foot tends to increase his deformity, while standing or walking helps to maintain his foot in good position. The cage, which consists of a small upper hoop, and a large lower hoop to which casters are fixed, is very useful at this stage. The upper hoop to some extent supports the child's weight, so that it can get about along the floor by using its feet as in walking.

When walking, these patients very often have a habit of turning in their feet. The reason of this is obvious when one remembers that the inward twist of the limb is not confined to the foot and ankle alone, but affects the whole leg. Swan has pointed out that the total deformity is an atavism, being the same as the condition which normally exists in the anthropoid apes. As in the latter, we find that the external malleolus is situated more to the front than in the normal human leg. In fact, to remedy this defect, he has devised an operation wherein the tibia is divided in its lower third, and the foot is then rotated outwards, carrying back with it the external malleolus. Another method of dealing with this inversion of the leg is by the use of Barwell's artificial muscles, applied so as to reinforce the peronei. But usually the tendency to turn in the feet while walking may be overcome by careful training. I have found that the simple expedient of bandaging both feet, with their outer sides against one long splint placed at right-angles to the limb, is an effective method of dealing with most of these cases. The splint need only be applied for a few nights to bring about the desired result.

At first the child is made to walk about in its stocking feet. Afterwards, especially in late cases, it is often necessary that he should be provided with a *Varus* boot. This has an inside steel, hinged at the ankle, extending from the heel to just below

the knee. To the outer side of the foot is attached an external malleolar strap; this is buckled over the steel, and tends to keep the sole everted. Sometimes it is only necessary to reverse ordinary boots, the child wearing the right boot on the left foot, and *vice versa*.

What I have said up to the present is specially applicable to the treatment of young children; but after the age of two or three years the plantar fascia frequently requires division; and manipulation is greatly aided by the occasional wrenching of the foot with Thomas's wrenches, the patient being under an anæsthetic. The application of a plaster of Paris bandage to hold the foot for a week or so in as good a position as can be obtained is a useful procedure after wrenching. Resection of bone is seldom resorted to here, except in patients over eight years of age. From the outer border of the foot a small wedge of bone is removed, consisting of the spur of the fifth metatarsal and the anterior part of the cuboid. The cure can then be completed by wrenching and manipulation, for in these cases there is always an osteoporosis and atrophy of the tissues.

In conclusion, I would emphasise the fact that, in order to render the limb serviceable, in congenital talipes equino-varus, even in adolescent patients, we rely more upon the gradual wrenching and manipulating the foot into shape than, by an extensive resection of bone, upon attempts to rectify the deformity.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this Journal. The Lecture for next week will be by William Thorburn, F.R.C.S., B.Sc.Lond., Hon. Surgeon to the Manchester Royal Infirmary. Subject: "Some Points in Connection with the Surgery of Gall-Stones."

## ORIGINAL PAPERS.

### THE DIGESTIVE DISTURBANCES OF RICKETS.

BY PROFESSOR A. B. MARFAN, M.D.,

Physician to the Paris Hospitals.

[SPECIALLY TRANSLATED FOR THIS JOURNAL.]

THE osseous deformities of rickets may be met with independently of any notable constitutional disturbance, though this is exceptional. The skeletal changes are almost invariably accompanied by sundry visceral troubles, anæmia, a certain degree of muscular debility, occasionally by nervous symptoms and usually by profound disturbance of the general nutrition. The frequency and intensity of these concomitant disturbances appear to justify the view that rickets is not a disease affecting only the bones, but that it is rarely a constitutional malady, *totius substantiæ*.

As soon as we try to define the relationship of these disturbances to the rachitic disease, however, we meet with difficulty. The connection between rickets, and this or that disturbance, may conceivably be of the nature of a fortuitous coincidence, a fertile source of error in observational science, even if we succeed in establishing a relationship other than coincidence between rickets and some particular state, it remains for us to find out whether the latter is the cause of the rickets or whether the state and the rickets are not both the outcome of a common cause, and this is often far from easy.

We have endeavoured to ascertain to what extent this is possible in respect of the concomitant phenomena of rickets, with the following results.

As a rule rickets is associated with disturbances of digestion, and on this coincidence is founded the most generally received conception of its ætiology. Yet these disturbances have not hitherto received much attention and their history is still somewhat obscure. For some years past I have been collecting data from private and hospital practice, and though cases are less frequently met with in the former they are more instructive than the latter, because we are in a better position to find out the antecedents and to watch the course of the disease.

These researches show that there are cases of rickets in which digestive disturbances are conspicuous by their absence but, as already pointed out, such cases are rare, more or less previous digestive disturbance being the rule. The disturbances may be divided into two groups: (1) Digestive disturbances that precede and accompany the onset of rickets, *i.e.*, the osseous changes, and (2) the dyspepsia of confirmed rickets.

The commonest form of the premonitory digestive disturbances is recurrent catarrhal gastro-enteritis. This may date from the commencement of life. The earliest symptom is diarrhœa, characterised by frequent motions—five or six in the 24 hours—these are liquid, grumous, green or mixed (a mixture of green, yellow and white matter) transparent and somewhat gelatinous. The diarrhœa may be accompanied by vomiting and a butyric odour of the breath. There is often some tympanites and vesicular erythema of the buttocks, possibly a slight rise of temperature, never however exceeding 101 deg. F.

Sometimes mild, sometimes pronounced, these disturbances last several days or a week or two seldom longer. This stage is followed by a period of calm, then we get a fresh outbreak, and so on for weeks or months.

In the intervals it is to be noted that the digestive functions do not return to normal for the dyspepsia persists more or less according as the infant is being brought up at the breast or otherwise. If bottle-fed, which is usually the case, the stools are light-coloured, soft, two or three a day, or there may be slight constipation. Even in the breast-fed infant the stools are still somewhat frequent, rather more liquid, and less homogeneous than normal. In both there is occasional puking and sickness.

Meanwhile the child does not gain in weight, indeed, may even lose flesh. The general health is possibly not very obviously affected, but it may happen that one of these attacks assumes the form of infantile cholera, in which case the loss of weight is very marked and the infant remains feeble for some time after.

It is in the course of this chronic dyspepsia that the first bony deformities usually make their appearance, between the sixth and twelfth months of life. During the initial stage the digestive disturbances persist for a time, but sooner or later they undergo a change.

In less frequent cases the digestive disturbances that precede rickets assume the form of dyspepsia with frequently repeated attacks of vomiting, obstinate constipation and retraction of the belly, or there may be spasmodic catarrh of the whole alimentary canal.

As the disease proceeds the digestive disturbances take on a different form, peculiar to this stage. The characteristics of the dyspepsia of confirmed rickets are the following: the appetite is capricious, there are periods of anorexia followed by periods of voracity. If we listen over the stomach after food has been taken we can elicit a distinct splashing sound, there is in fact a state of hypopepsia with abnormal fermentations.

The rickety artificially-fed infant is usually constipated and expels dry motions with some difficulty, the motions being hard, white, foetid and often laden with phosphate of lime. In the breast-fed infant the motions may be normal, but here again there is usually constipation with marked fœtor.

As these symptoms and the osseous changes progress the abdomen becomes large and flabby. It is resonant on percussion, but the resonance is muffled, very unlike that of tympanites.

This flabbiness of the belly is accompanied by more or less pronounced elongation of the intestines which become thinned, especially in respect of the muscular coat, in fact there is relaxation of the muscular walls.

This state lasts as long as the rickets, and does not improve until the latter begins to subside.

It will be seen then that two kinds of digestive disturbances are met with in connection with rickets. The first, prodromal or initial, belong to the category of recurrent gastro-intestinal catarrh, the second, a special form of atonic dyspepsia with a big, flabby belly.

Now these two forms do not represent two successive phases of the same process, the dyspepsia of confirmed rickets is not the effect, the natural consequence, of the premonitory catarrhal enteritis, in fact, they are independent of each other. This is shown by the fact that rickets may supervene in infants whose digestion is apparently normal, the symptoms of rickety dyspepsia not supervening until the disease is well advanced.

The form of dyspepsia associated with the big, flabby belly is virtually peculiar to rickets, and it is not difficult to understand its causation. The intestinal elongation and the big, flabby belly are, indeed, only part of the general muscular atony associated with rickets.

The preliminary catarrhal gastro-enteritis is usually the consequence of improper feeding, especially ill-digested milk. We have remarked that these preliminary digestive disturbances do not necessarily precede the onset of rickets, but they are too frequent for there not to be some connection between the two.

The general view of the causation of rickets, is that it is due to improper feeding, so that the premonitory dyspepsia and the osseous changes are regarded merely as successive effects of the same cause. This view, however, must be modified to meet the difficulty raised by the occurrence of rickets in breast-fed infants whose feeding is not open to criticism. It would seem indeed, that digestive disturbance, of whatever origin, may determine rickets, and if the disease be more frequently met with in bottle-fed infants this is due merely to the fact that digestive disturbances are more liable to occur under these artificial conditions.

This view, however, is only true in part, for I am satisfied that rickets may be due to causes other than defective alimentation. I have met with cases of rickets in breast-fed infants without any previous history of digestive disturbance, so that in such cases the rickets could not possibly be ascribed to gastro-enteritis or dyspepsia.

Now it is unquestionable that rickets is far more commonly met with in bottle-fed infants than in the breast-fed, yet I am far from convinced that artificial feeding is *per se* capable of inducing rickets. I believe that this only plays the part of a predisposing agent. The primary cause of rickets is to be found in all forms of chronic intoxication, occurring at a certain phase of ossification and hæmatopoiesis, a phase that extends from the last months of intra-uterine life to the end of the second year of extra-uterine life, during which the modi-

fications of the bone marrow, provoked by these diseases, may interfere with the building up of bony tissue. If we inquire closely into the antecedents of a rickety subject, it is very rare not to discover some infection or chronic intoxication underlying the origin of the bony deformities. The infections that we have met with in this connection are: chronic toxi-infective digestive disturbances, either acute or recurrent, hereditary syphilis, protracted broncho-pneumonia and chronic pyodermitis. These causes are the more active when they are operative in a predisposed subject, and one of the most powerful predisposing causes is unquestionably artificial feeding and heredity, plus unwholesome surroundings and deprivation of light and fresh air.

This explanation is the only one that accounts for all the facts in connection with rickets, notably its occurrence in breast-fed infants free from any preliminary gastro-enteritis. There must be concurrence of several factors for the production of rickets, foremost among them being chronic infection and predisposition.

## GENITAL TUBERCULOSIS.

By PROFESSOR LÉGUEU,

Agrégé at the Faculty of Medicine of Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

Most frequently met with in adults, genital tuberculosis may attack any part of the reproductive apparatus.

It reveals its presence by purely objective signs. It may take the form of an attack of acute epididymitis, coming on quite suddenly, sometimes without any apparent cause, sometimes following a blow or an effort of some kind. Or there may be a running from the urethra independently of any previous history of blennorrhagia, the discharge consisting of serous, grumous pus, this variety being almost invariably associated with lesions of the prostate or seminal vesicles. Lastly we may get chronic tuberculous epididymitis, the form most frequently met with.

The tail of the epididymis is always the first to suffer, never the head. It becomes tubercular, and circumscribed areas of hardness can be felt on its surface. As a rule the disease runs a painless, indolent course, though in cases in which the disease develops more rapidly there may be some pain.

No adhesions can be made out unless there be threatening suppuration, or when it has already suppured, or in presence of a fistula. The tunica vaginalis is often distended with fluid in variable amount, constituting a form of hydrocele; this may accompany tuberculous epididymitis, or it may complicate tuberculosis of the testicle itself. The latter form, which results from infection of the blood, attacks the parenchyma of the gland, disseminating a few isolated tuberculous foci that give no outward and visible sign of their existence. It is only on cutting through the testicle that we discover these internal tubercles which explain the occurrence of hydrocele of the essential form, so-called because the actual cause of the trouble eludes our observation. The vas deferens is affected in its course, but more particularly at its termination. Above Scarpa's triangle it may be felt as an indurated cord (peridiferentitis). Tuberculosis of the prostate is not painful, tender, or increased in size. The prostate contains a number of circumscribed isolated hard nodules, perceptible on palpation. The seminal vesicles, which suffer most damage at their orifices, feel hard, as if injected with tallow.

Genital tuberculosis may lie latent for years in its

course towards suppuration. Deeply-seated lesions, as in tuberculous prostatitis, are more apt to suppurate early. When suppuration takes place we get a whole series of secondary infections, cavities, fistulæ, etc. Nevertheless, the disease is curable in favourable cases, although it constitutes the gravest form of localised genital tuberculosis. In the epididymis and prostate the little indurated nodules remain perceptible on examination, but the caseous matter is gradually replaced by fibrous tissue. In blennorrhagia the areas of induration, on the contrary, end by disappearing. It is unnecessary to add that if the kidney and lungs are attacked concomitantly the disease is thereby greatly aggravated, more, however, on account of its generalisation than by reason of its localisation in the genital organs.

Patients suffering from genital tuberculosis come to consult us under three different sets of conditions: It may be on account of the urethral running and loss of flesh. We must begin by excluding blennorrhagia and its complications and consequences. Having done this, we may contemplate the possibility of its being due to tuberculosis. In other cases there is a perinæal fistula, discharging either in the perinæum or near the urethra. Rectal examination and the introduction of a sound will enable us to discover the cause of this in deeply-seated suppurative lesions of the prostate. Lesions of the testicle may be masked, as already shown, by the existence of hydrocele, the effusion into the tunica vaginalis being consequent upon epididymitis or central tubercle, the latter eluding the ordinary methods of exploration. In presence of a voluminous hydrocele, when palpation of the epididymis, which is placed behind, is not practicable, we must carefully examine the testicle on the opposite side. The presence of nodules on the epididymis will clinch the diagnosis, while rectal examination will settle the question whether the prostate is involved.

The diagnosis is by no means always easy. Various difficulties may present themselves. In some instances we get a history of acute epididymitis following a blow or an effort. This detail is one of very great importance, for we must not attribute to the traumatism what in reality is dependent upon the tuberculosis. As a matter of fact, there is no such thing as orchitis from strain. What we really get is tuberculous epididymitis that has become acute following a strain. This remark also applies to direct traumatism. The latter may, no doubt, determine a certain degree of congestion, but how are we to explain the localisation of the traumatic inflammation in the epididymis? The conclusion to be drawn is that traumatism *per se* cannot determine orchitis.

When the tuberculous process attacks the epididymis the diagnosis has to be differentiated from blennorrhagia, and this is not invariably an easy matter. We need not refer to syphilis, since no confusion is possible in this connection. When syphilis involves the epididymis it attacks the head of the organ, whereas, as I have pointed out, tuberculosis attacks the tail. Tuberculosis and blennorrhagia, however, both attack the tail of the gland, so that we cannot rely on the localisation, which is the same in both instances, to guide us. Some importance attaches to the insidiousness of the onset and the indolence peculiar to tuberculosis, but one meets with cases of blennorrhagic epididymitis that run a latent, painless course, for all cases of blennorrhagic epididymitis are not accompanied by pain. The element pain, therefore, does not help us very much in distinguishing between tuberculosis and blennorrhagia. It is claimed that the existence of adhesions militates in favour of

tuberculosis, and no doubt this is true as far as it goes, but, apart from imminent or actual suppuration, there are no adhesions. Nor do the lesions of the vas deferens assist us materially, because although there is inflammation of this canal in tuberculosis this is also met with in blennorrhagia.

In short, there are only two signs that justify the diagnosis, viz., the state of the urethra and of the deep parts. A healthy urethra that only discharges a drop or two of liquid after the ingestion of irritating fluids, such as beer, cannot conceivably be blennorrhagic. If necessary, we must look for the gonococcus under the microscope, and when it is absent we may conclude in favour of tuberculosis. Rectal examination will enable us to discover nodules of tubercle in the prostate, if present, so that, having excluded blennorrhagia, the diagnosis becomes easy.

The treatment is purely medical. A season at some watering-place—Biarritz, Salies de Béarn, etc., along with the usual tonic medication, will often greatly improve matters. One sees cases of tuberculous epididymitis in which the induration retrogress and disappear in the course of a few weeks, the patients returning completely cured. Castration, which used to be recommended in this affection, is a detestable operation, for it is quite insufficient, seeing that it does not prevent the spread of the disease, while it is excessive in that it entails removal of a testicle which may turn out to be healthy. At most, in presence of fistulous lesions, we might intervene for the purpose of removing the epididymis. This partial operation has the advantage of removing the diseased tissue while leaving intact the internal secretion of the testicle. As for prostatectomy and removal of the seminal vesicles on account of tuberculous disease it is extremely rare for either of them to be necessary or desirable to have recourse thereto.

## THE CONTAGION OF LEPROSY.

By ALBERT S. ASHMEAD, M.D.,

Canadiensis.

As a strong advocate for the absolute separation of the new-born from their leprous parents, I may perhaps be permitted to observe that, while the statistics of percentage of contamination which Dr. Sand presented to the Bergen Second International Leprosy Conference (quoted in an editorial of Oct. 30th) is apparently "small," there is still much danger of contagion to every child left to the care of its leprous mother.

It may here be pointed out how those statistics of Dr. Sand may be misleading, because 138 leprous mothers had, among their 533 children (even when all were born after the women had become leprous, only 56 leprous offspring might only mean that enough time had not been given to all of them for the development of the contamination, which might remain with them, in fact, all their life. While I do not believe much in direct transmission of leprosy, unless other factors are present besides the inoculation of the germ, I certainly do believe that some intermediary host, which, perhaps, only momentarily could carry the germ, has a thousand times more chance to inoculate a child in arms, and otherwise most closely associated with its maternal focus of possible contamination, than perhaps it could in any other close family associations of two individuals, one well, the other infected.

What surprises all of us most is not the mere fact of realisation of the contagion, but the difficulty of explaining the immunity of any human body, and especially a child of a leprous mother, in spite of contagion. Some of us believe that this

last is due to the human milk diet, for no child, while at the breast, ever became a leper.

Varigny has well said: "In order to understand this, we must take into account that microbial diseases develop under two conditions: it is necessary that the microbe be living in good state, and that it penetrates into the organism under favourable circumstances." There is also required some predisposing medium *chemically* adapted to the life and nature of the microbe. This medium no doubt varies according to difference in epochs, races and climates, affecting perhaps the presence and activity of some intermediary host, and for the same reason immunity may be present in a body already inoculated, and remain so for years, until the individual requirements for the development of the virulent character of the living microbes present themselves. Then, and not till then, leprosy appears, and we say this one is a leper, although he was not known as such from the moment of his inoculation to the later real manifestation of symptoms of the disease. Or the organism may change, or lose altogether its resistance to the development of the germ into activity within a short period in after-life of the individual, and remain more or less, or absolutely, inert, as it surely does from birth to two and a half or three years of every infant's life. Hence the difference in resistance to contagion; hence the exceptional facility which it finds in certain cases, regardless of age. Here we have also some light thrown on those cases in which the contagion has met with such difficulties that some physicians have been tempted even to deny it altogether.

Are the statistics quoted from Sand any more important than those percentages that might be quoted concerning children born of, or in close association with, syphilitic mothers or of consumptives? Not one bit.

In 1898, Dr. Sand, in reply to my inquiry, wrote me of a carpenter who became a leper in Chicago. I thoroughly investigated this man's contagion. He afterwards died a leper in Reitfardet Asylum, Norway, under Dr. Sand's care. He had come to this country from a non-leprous family; even his home district was not leprous, and he lived for twelve years in a Norwegian boarding-house in Chicago before becoming even an incipient leper.

Sand and I both determined, after the fullest investigation by Sand in Norway and myself in Illinois, that he had become contaminated in Chicago. And although he may have carried the germs all those twelve years, or perhaps more after Norwegian inoculation, before he had emigrated, yet we determined that he got his disease in Chicago, probably through his own countrymen's habit of importing old clothes from Norway, in which possibly leper bacilli were still living in free existence, or perhaps carried by a *louse* as intermediary host.

At any rate, if he did not get the contagion in Chicago, he had certainly carried the germs in his own flesh *safely* for at least twelve years.

In 156 patients of Sand's in his asylum, 90 were tubercular lepers and 66 anæsthetic. In these last the risk of contagion from a leprous mother to her child would be scanty. And yet it might happen, for we are still ignorant of the exact method of transmission of the germs. Dr. Sand formerly was of opinion that leprosy is contagious, "just like phthisis is," and he believes that the bacilli may lie dormant in the system "for as much as twenty years."

But the most important part of Dr. Sand's former opinion was, that "children and old people are most liable to contract leprosy"; and that

these, "*especially the children*," should be "*especially protected*" against contagion.

He thought that there is something in the system which "may stir the bacillus into activity"—"in one year or twenty after inoculation." Or perhaps it might never be stirred into activity.

Sand's more recent statistics do not affirm that leprosy can absolutely *not* be communicated from a mother to her child. And even if he believes that the disease is not contagious "from individual to individual," he surely must still believe in contagion. And his statistics now, in fact, only more strongly confirm the necessity of *absolute separation of children at birth from their leprous parents*, to save those very 56 children of the 138 leprous mothers from the surely possible contamination; for a percentage of 56 of child-infections out of 533 is *much greater than that by any other special association in the family life*; and we all must admit that this disease spreads itself mainly by family contagion of some sort or other.

### THE CHILD CRIMINAL. (a)

By W. C. SULLIVAN, M.D., R.U.I.,

Medical Officer, H.M. Prison, Holloway.

WHEN the Committee of this Society did me the honour of asking me to open a discussion on the Child Criminal, I did not accept the invitation without a full sense of the responsibility I should incur in venturing to address an audience of experts on a subject of which I can pretend to know only one narrow aspect, and that aspect very imperfectly. But though I thus realised to the full the difficulties of my task, I did not feel that I should be justified in refusing to do what little lay in my power to help in bringing forward for the specific consideration of your Society a question, the solution of which, I am convinced, can only be found by the combined efforts and the combined knowledge of the educationalist and the student of criminology.

It is hardly necessary to say that anyone who has constantly to deal with the adult criminal is forced by his daily experience to think a good deal and to inquire a good deal about the child from whom that adult has developed; and as a result of his thinking and his inquiries he will most probably come to a conclusion which is not of very startling novelty, namely, that amongst the criminals whose history he has investigated there are some whose native disposition made it almost inevitable that they should become criminal, and others, on the contrary, who became criminal merely because circumstances gave that direction to their normal aptitudes. While of others, again, and these the large majority, he will find it hard to decide whether temperament or accident had most to do with the result. According to this view, then, though it often happens that the child who grows up to be a criminal is simply an ordinary child with the average endowments of his fellows in character and capacity, it may be, on the other hand, that he is a child whose conduct from quite early in life reveals an abnormal temper and very often a defective intellect, so that he is marked out almost in infancy as belonging to a morbid, a degenerate type. It is children of this latter sort that we ordinarily mean when we speak of criminal children; and in accordance with that common and convenient interpretation of the term, is to the examination of the characteristics of such moral defectives that I propose to devote the greater part of the present paper. As a preliminary, however, to the consideration of this main theme, it will, I think, be desirable to invite your attention for a few moments to some points bearing on the general question of criminal tendencies in childhood and youth, which will help us to see our special subject in its true perspective and to grasp the relation of abnormal development to criminal habits.

(a) Read at a meeting of the Child Study Society, November 18th, 1909.

In this connection we have first to take note of the obvious truth that in a certain sense every child is, and ought to be, a criminal. What I mean is, of course, that most of the conduct which we should term criminal in an adult is the result of quite normal impulses, and we only qualify it as criminal because in the given circumstances these impulses ought to have been inhibited, held in check by moral and social restraints; so long, therefore, as these restraints are feebly or imperfectly organised, as they are in the child, the impulses will naturally issue in accordant conduct, whether that conduct, judged by adult standards, is culpable or not. Take, for instance, the impulse which accounts for an overwhelming proportion of the total volume of crime, that is to say, the acquisitive impulse. We have only to watch the play of that impulse in the average baby to be convinced of the strength of our natural aptitudes for thieving. And if we now, with this impression fresh on our minds, turn to a later phase of development, when the baby has become a youth and has reached an age which makes him amenable to legal punishment, though his growth is still unfinished and his power of control over his impulses is still weak and uncertain, we see that the failure to restrain this acquisitive impulse is the cause of a great deal of conduct which is, in fact, recognised and treated as crime. I do not want to weary you with figures, but I may remind you of the well-established fact that during youth and adolescence the proclivity to crimes of acquisitiveness is far greater than at any other period of life; in this country, for instance, a fourth of the persons convicted of larceny are under 16 years of age, and nearly half are under 21; or, to look at the matter in what may be a more suggestive way, we may put it that the proportion of persons convicted of indictable offences in relation to the total population is highest in the age-period 16-21, when it amounts to 321 per 100,000, that between 12 and 16 it amounts to 261 per 100,000, that in the period 21 to 30 it falls to 245, declining rapidly then in each succeeding age-group. These figures, of course, are simply a statistical expression of the fact that throughout the period of development the will in its higher controlling form is imperfectly organised, and as a result of this immaturity the individual is relatively lacking in the power to check and govern his appetites so as to bring his conduct into harmony with the legal and ethical standards of the community. And in this connection we have, of course, to remember that development in man is very slow, relatively slower than in any other animal, in accordance with the general rule that the more complex the organism the longer it takes to reach maturity. The ossification of the skeleton, as you know, is not completed till about the twenty-fifth year, and it is only about that time, too, that the organic functions attain their perfection of rhythm, so that a good third of human life is thus given up to the process of growth. And if this is true of the grosser activities of the body, it is, of course, doubly true of the latest and most complex development of nervous function, the coordinating and controlling will. It is, then, fairly obvious that some degree of inhibitory feebleness, some lack of self-control is natural in adolescence, and hence we must regard the criminal activity, which we find to be so marked at this period of life, as being to a certain extent almost a normal, a physiological manifestation. I need hardly remind you in passing that this view has recently found practical recognition in this country, and with peculiarly fortunate results, in the initiation of the Borstal System, under which the adolescent offender is dealt with by educative and reformatory methods, designed to prevent the fitful and unregulated temper of immaturity from becoming fixed in the criminal habit.

Now, seeing how slowly and gradually the restraining power of the will is built up in youth and adolescence and on what infinitely varied and complex conditions its growth may depend, we can readily understand that the possibilities of the process suffering arrest or perversion must be very considerable; and when we remember, as we all can from instances within our own ex-

perience, to what an extent faulty education can retard or altogether prevent the acquisition of habits of self-control, and how easily such habits, when still recent, may be weakened or lost, as, for instance, in conditions of fatigue or ill-health—when we bear all this in mind we shall have little difficulty in admitting that the development of the more elaborate inhibitions which depend on the force of the social and moral feelings and ideas, must very often be so much checked and modified as to be hardly recognisable. What we have to infer from these considerations is, therefore, that neither the appearance of criminal tendencies in childhood—for that is quite normal—nor the persistence of such tendencies as a criminal impulsiveness in adolescence and adult life—for that may be merely a result of bad environment—neither of these facts can be regarded as a sufficient proof of defective organisation, of innate incapacity for social adaptation. A boy may be self-willed, violent, capricious, he may even be a bit of a liar and a bit of a thief, without going outside the limits of the normal in boy character; and this same boy may, if neglected, grow up into a hooligan—and that is, in fact, the history of the majority of habitual criminals—but for all that he may not have been a criminal child in the sense in which we are using the term here. Before we can bring an individual into that category we must have evidence that his conduct is really morbid, that it is related to a disorder of nervous organisation. It is to the consideration of that evidence that we have now to turn.

Broadly speaking, this evidence is of two sources; it is either given directly by the character of the emotional and impulsive disorder, or it is inferred from other indications of disease or defect. And first as regards the disorder of conduct and feeling. Here, of course, as in all contrasts between the healthy and the morbid, the normal and the abnormal, we are dealing only with differences of degree and not with differences of kind. The morally defective and the ordinary child are both moved by impulses which are essentially the same in nature, and the failure to restrain these impulses is due in both to the absence or weakness of the same controlling centres. The morally defective, the criminal child, does not reveal his morbid character by new impulses but by the disordered and exaggerated play of the normal impulses, finding expression in modes of feeling and conduct which depart more or less widely from those of the average child. In this relation, however, it has, of course, to be remembered that the moral and mental growth of the child, like the development of his lower physical powers, is not uniform nor uniformly progressive; various nervous functions develop with varying degrees of rapidity in different individuals, and this will often result in a temporary appearance of irregularity and excess which must be distinguished from the irregularity and excess that are due to permanent defect. Subject to the reservation which this implies, we may look with suspicion on any marked excess in irritability, in deceit, in cruelty or destructiveness, especially when associated with any precocious sexual tendencies. Very frequently this vicious temper is shown in several directions, so that the future criminal signalises himself by the multifariousness of his wickedness. And this trait, it may be remarked, persists into adult life, and is sometimes a valuable sign of the pathological disposition in a criminal. For instance, one moral defective whom I have known for many years, and who exhibited criminal tendencies in several forms in childhood, when he graduated as a gaol-bird later in life, several sentences for quite a variety of offences—for theft, for vagrancy, for assault, for attempted suicide, for arson, and for a whole series of different offences against morals. Like many delinquents of his class, this man displayed a monkey-like mischievousness in all his criminal acts which was very characteristic of his mental debility. Children showing this vicious precocity are also in most cases intellectually defective, though they may be so to only a very slight degree—sometimes, indeed, their weakness of judgment is shown merely in their lack of critical insight in preparing or excusing their misdeeds. In such cases the

morbid character of the child may be most evident in his relations with his school-fellows which foreshadow his social inadaptability; his defects come out more in play than in lessons, and his educational standard may tell less about him than the nick-name bestowed on him by his comrades.

The intellectual weakness to which I have just referred is so intimately related to the moral defect in the criminal child that it must count as the most important indirect evidence of morbid constitution. I do not, of course, mean to say that there is any inter-dependence between the moral and the intellectual development; the obvious want of correspondence between the degree of deficiency in either sphere would, indeed, suggest quite the opposite view. Probably the truth of the matter is, that it needs intellectual as well as ethical defect to bring the degenerate to prison, so that the cases where moral idiocy co-exists with normal or superior intellectual power—if such cases there be—would be met with not in gaol, but in that wide territory which separates legal from moral delinquency. However that may be, it is certainly the rule to find that the criminal defective has given some evidence of intellectual weakness in childhood—he has failed, for instance, to get beyond a very low standard at school, or he has never been able to learn some particular subject.

With or without obvious intellectual debility, we often find in criminal children a further sign of morbid constitution in the presence of epilepsy, and perhaps even more frequently than the actual neurosis we meet with the typical epileptic character. This, as you know, is shown in an excessive irritability and changeableness of temper, in sudden and extreme alternations of feeling and in violent impulsiveness—all of these conditions bearing the mark of periodicity which belongs to the manifestations of epilepsy. This character is found with special frequency in the children of the alcoholic. In other children, again, the moral debility has a hysterical colouring, and in these cases the intellectual weakness may be very slight; the child does well enough at lessons, but he reveals his morbid temper by various extravagancies of conduct, notably by fantastic lying, and sometimes, too, by vagrant fits, when he may stray away from home for days and perhaps only vaguely remembers what has happened to him. We often get a history of this sort in neurotic swindlers. In yet other cases the nervous disorder is characterised chiefly by a lack of balance, a want of mental harmony; and in many individuals of this type eccentricity of temper is more evident than moral defect, which may be trifling in degree and limited to a few impulses. These degenerates have what Maudsley has so aptly termed the spasmodic diathesis; they are often subject even in early youth to obsessions and impulses generally of an absurd sort, but occasionally leading to criminal acts.

Finally, to complete this review of the several groups of criminal children, we may refer to those cases where the evidence of mental and moral abnormality is not apparent until about puberty; as a rule, we have then to deal with actual insanity, and such cases only interest us here because it so often happens that the disorder of conduct and feeling precedes the disorder of thought by months or even years; the character and manners change perhaps when the boy is 13 or 14 years old, and he shows vicious and criminal tendencies, the real meaning of which only becomes clear when he develops delusions or goes raving mad at 16 or 18. Sometimes, of course, mental disorder of this kind affects children who have already shown signs of abnormality, and in other cases the bad family history raises a strong presumption of the existence of innate deficiency.

In all the groups which we have spoken of, it is usual in a large proportion of cases to find evidences of physical defect or deformity. Long lists of these so-called "stigmata of degeneracy" are to be found in the literature of criminal anthropology, and several authors have attached very great importance to their presence. So far as my personal experience goes, I should say that they have relatively small signifi-

cance, though in some cases their occurrence in marked degree and in large numbers may help to prove that emotional and impulsive disorders are due to defective organisation and not to merely temporary irregularity of development.

And now, if I have not out-wearied your attention, I should like, before bringing this paper to a close, to touch for a moment on one or two practical inferences to be drawn from our discussion of this question. The first and most important of these inferences is so obvious that it is hardly necessary to indicate it: it is that the problem of the criminal child is essentially a particular aspect of the general problem of feeble-mindedness, and that on that account the arguments for the segregation of the weak-minded and for the adoption of methods to prevent the propagation of defective stock—the prescriptions, in fact, of what Dr. Saleeby has aptly termed negative eugenics—apply to the moral as well as to the intellectual imbecile. If anything, indeed, they apply with more force to the morally defective, since these latter not only suffer from the unfitting environment of the normal, but themselves react injuriously upon that environment and become centres of corruption and disorder, the intensity of their vicious impulses giving them an easy ascendancy over the pliant and mutable temper of the ordinary child. The frequently collective character of juvenile crime suggests how powerful this bad influence may be. More than that, by early segregation these individuals are protected from the stimuli which provoke their vicious tendencies, and so a chance is given for developing whatever capacity for moral and social feeling they may have, and most of them have at least a rudiment; even in prisons it is but rarely that one meets with cases of such moral monstrosity, with "born devils," on whose nature nurture can never stick."

And this fact leads me to the second main conclusion which I should like to submit to you, namely, that we must be very cautious and very hesitant in affirming the existence or the degree of moral imbecility; the results of bad nurture are sometimes exceedingly like the results of bad nature, and to distinguish between them is often a difficult, and may be, an impossible task.

## PROPOSED STERILISATION OF CERTAIN DEGENERATES.

By ROBERT R. RENTOUL, M.D.

It will be of interest to those who agree to my proposal—made in 1903—that one way of lessening the ghastly total of degeneracy would be to so surgically operate upon certain degenerates that they could neither beget nor conceive—is gaining ground.

Already two States in America have adopted my proposal.

On January 1st, 1909, there were, in England and Wales, no fewer than 128,787 officially certified insane; and an increase of 2,703 in the year. But there are a great many at large who are not "officially" reported. In 1859 there were only 36,762 certified insane.

The insane rate since then has increased by 250 per cent., while the population has increased by 81 per cent., and evidently—judging by our "do-nothing" policy—we are quite content to go on marrying and breeding more and more degenerates; and to expend yearly millions of pounds sterling upon these—an expenditure which gives us no results.

It may be that new proposals in an *old* country are always the product of an ill-balanced mind, or are to be labelled heretical. But on February 10th, 1907, the legislature of the State of Indiana passed the following Act:—

"An Act entitled an Act to prevent procreation of confirmed criminals, idiots, imbeciles, and rapists—providing that superintendents or boards of managers of institutions where such persons are confined shall have the authority, and are empowered to appoint a committee of experts, consisting of two physicians, to

examine into the mental condition of such inmates.

"Whereas heredity plays an important part in the transmission of crime, idiocy, and imbecility. Therefore, be it enacted by the General Assembly of the State of Indiana, that on and after the passage of this Act, it shall be compulsory for each and every institution in the State entrusted with the care of confirmed criminals, idiots, rapists, and imbeciles, to appoint upon its staff, in addition to the regular institution physician, two skilled surgeons of recognised ability, whose duty it shall be, in conjunction with the chief physician of the institution, to examine the mental and physical condition of such inmates as are recommended by the institutional physician and board of managers.

"If in the judgment of this committee procreation is inadvisable and there is no probability of improvement of the mental condition of the inmate, it shall be lawful for the surgeons to perform such operation for the prevention of procreation as shall be decided safest and most effective. But this operation shall not be performed except in cases that have been pronounced unimprovable."

Again, on August 12th, of this present year, the State Legislature of Connecticut enacted:—

"An Act concerning operations for the Prevention of Procreation.—Be it enacted by the Senate and House of Representatives in General Assembly convened:

"Section 1.—The directors of the State prison and the superintendents of State hospitals for the insane at Middletown and Norwich are hereby authorised and directed to appoint for each of said institutions, respectively, two skilled surgeons, who, in conjunction with the physician or surgeon in charge at each of said institutions, shall examine such persons as are reported to them by the warden, superintendent, or the physician or surgeon in charge, to be persons by whom procreation would be inadvisable.

"Such board shall examine the physical and mental condition of such persons, and their record and family history so far as the same can be ascertained, and if in the judgment of the majority of said board, procreation by any such person would produce children with an inherited tendency to crime, insanity, feeble-mindedness, idiocy, or imbecility, and there is no probability that the condition of any such person so examined will improve to such an extent as to render procreation by such person advisable, or, if the physical or mental condition of any such person will be substantially improved thereby, then the said board shall appoint one of its members to perform the operation of vasectomy or oöphorectomy, as the case may be, upon such person. Such operation shall be performed in a safe and humane manner, and the board making such examination, and the surgeon performing such operation, shall receive from the State such compensation, for services rendered, as the warden of the State prison or the superintendent of either of such hospitals shall deem reasonable.

"Section 2.—Except as authorised by this Act, every person who shall perform, encourage, assist in or otherwise promote the performance of either of the operations described in Section 1 of this Act, for the purpose of destroying the power to procreate the human species: or any person who shall knowingly permit either of such operations to be performed upon such person—unless the same be a medical necessity—shall be fined not more than one thousand dollars, or imprisoned in the State prison not more than five years, or both."

There need be no objection to such an operation as is here suggested. It is very simple, practically painless, makes no difference at all to the bodily functions, and has no ill-effects of any kind. It prevents nothing but the power to procreate. It is the outcome of modern scientific knowledge, and must not be confounded with older and much more drastic methods.

In 1905 the Houses of Representatives and the Senate of the State of Pennsylvania passed a Sterilisation Bill, but the Governor of the State refused to sign it, evidently holding that further time was required. But from what correspondents in the States told me, there is every likelihood of many States following the practical example of Indiana and Connecticut.

In this country the cry is often—"Let me alone"; "Don't worry us"; "Wrongs will right themselves"; or, "I needn't worry; things will last my time." Such a mixed policy of hypocrisy and slavish desire to tread the beaten track will not work for good.

We howl about the increase of paupers. Yet we allow the pauper to leave the workhouse to get married. We howl about the increase of criminals. Yet we allow criminals to marry and to beget more criminals. And we howl about the increase of insanity and the feeble-minded. Yet we allow these to marry and to beget offspring fully qualified to perpetuate the weak-mindedness of their progenitors. Surely a noble and worthy national policy!

Some time ago I called attention to the fact that five feeble-minded women had given birth to fifteen feeble-minded infants(a). Later still, Dr. Potts stated that in one workhouse 16 feeble-minded women had given birth to 116 idiot children. Dr. Branthwaite, in his annual report (for 1905) on Inebriate Homes, states that 92 habitual inebriate women had had 850 babies.

Is it not time we took some definite action in this great national question of needlessly breeding more and more degenerates? Our present inaction is based only upon hypocrisy and cant, and has no reference to the unnecessary sufferings of so many degenerates.

## OPERATING THEATRES

### KING'S COLLEGE HOSPITAL.

CASE OF EXTRAVASATION OF FÆCES.—MR. PEYTON BEALE operated on a man, æt. about 40, who had been admitted the same morning, with the following history: He had been under the care of Dr. Branwell, at Penzance, for some months. It appeared that he had been complaining of some very indefinite abdominal pain, and although repeated careful examinations had been made, there was absolutely no evidence to show to what this pain was due. It could be realised how unimportant it was, since the doctor and the patient came to the conclusion that the pain was of a "nervous" origin. There had been some constipation, but this apparently was not bad enough to give rise to any real trouble. The history obtainable on admission from the patient was as follows: For some few days prior to admission he said he had noticed that his urine was "dirty": he said it was greyish in colour, and contained small particles; he also said that the flow of urine was not continuous. Two days before admission the doctor found that the urine contained liquid fæcal matter: he also observed that the patient had a small swelling beneath the skin of the abdominal wall just above the symphysis pubis. It was quite clear that at this time the patient was suffering no pain or inconvenience, and was getting about his work as usual. On the following day (one day before admission) the abdominal swelling was larger, the skin over it being slightly flushed; there was no temperature, and the patient appeared in very good health. He was sent up from Penzance by the night train, and walked into the hospital the next morning. On admission he was a perfectly healthy, robust-looking man, very well nourished, complaining of nothing but some discomfort on passing urine. When he micturated, liquid fæces and urine, accompanied by a large amount of sulphuretted hydrogen, passed from the urethra. Just above the pubes there was a tense hemispherical swelling about five inches in diameter, painful on palpation; the skin over it was red, and fluctuation was felt. The patient was taken into the theatre and anaesthetised, and after the usual preparation, a vertical incision was made into the swelling, from which about half-a-pint of liquid fæces only escaped. A cavity about the size of an ordinary orange was found between the superficial fascia and the aponeurosis of the external oblique. The walls of the cavity were very oedematous and sloughy in parts. Upon irrigating the cavity thoroughly, an aperture about three-sixteenths of an inch in diameter was found passing

(a) See "Race Culture, or Race Suicide?" Second Edition.

downwards and backwards. A probe inserted into it passed into the bladder, and through the aperture liquid faeces and blood oozed up. Under the circumstances, it was clear that the only course which could be reasonably pursued at this time was that of draining the bladder. The patient was, therefore, at once placed in the lithotomy position, and Cock's operation performed. This consisted of a median perineal section, the left forefinger being placed in the rectum, the knife being inserted in the middle line of the perineum half-an-inch in front of the anus, with the cutting edge forwards; the knife was plunged in opening the posterior urethra, the right forefinger was then inserted, tearing open the urethra until the cavity of the bladder was reached. A fair amount of urine and liquid faeces escaped, and there was some bleeding from the congested prostatic plexus of veins. A rubber drainage tube one inch in diameter was introduced into the bladder, and gauze was firmly packed into the small space between it and the edges of the wound.

After this the patient was extraordinarily well for the next three days. As he was then passing all faeces through the bladder drain, it was decided to perform an abdominal section so as to ascertain the cause of the trouble. The abdomen was opened along the outer edge of the right rectus, and on exploring the interior the upper part of the sigmoid flexure was found adherent in the middle line to the abdominal wall in front and to the bladder below. On passing a probe through the original abdominal wound, it became clear that there was an orifice about half-an-inch in diameter in the sigmoid, communicating upwards with the original abdominal wound, and downwards with the bladder. After a careful dissection through adhesions, the sigmoid was brought outside the abdomen through the original abdominal incision. Immediately below the perforation there was a hard stricture; this and the perforation were at once excised; the bowel was perfectly healthy half-an-inch beyond on either side, the length of sigmoid excised being only about an inch and a-half. The edges of the sigmoid were then brought together by an end-to-end anastomosis, and the junction replaced within the abdomen, which was thoroughly irrigated. The aperture in the bladder could be reached, but could not be sutured. As the bladder was thoroughly draining through the perineal wound, a gauze packing was introduced between the bladder and the newly joined sigmoid. No report, Mr. Beale said, has as yet been received as to the nature of the stricture in the sigmoid, but from its appearance and from the general condition and history of the patient, it probably resulted from a localised ulceration possibly due to a dilated sacculus of the sigmoid, which had become adherent to the anterior abdominal wall, on the one hand, and the bladder on the other.

We hope to give Mr. Beale's further remarks on this interesting case in a later number.

## TRANSACTIONS OF SOCIETIES.

### ROYAL ACADEMY OF MEDICINE IN IRELAND.

#### SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, DECEMBER 3RD, 1909.

The President, HENRY JELLETT, M.D., F.R.C.P.I., in the Chair.

#### EXHIBITS.

DR. GIBSON exhibited a specimen of myomatous uterus with necrosis of one large tumour and carcinoma of the endometrium. The patient from whom the uterus had been removed a few weeks previously, was over sixty years of age, and twelve years past the menopause. She knew that she had the tumour for many years, and had been given to understand that it would never do her any harm after the change of life. She had never been pregnant, and enjoyed good health

up to four weeks before he saw her, when she suffered from a severe attack of uterine hæmorrhage. She had not had any discharge from the menopause to that time. She had no pain, and except that she thought she had been getting thinner for the past five or six months, she noticed no change in her general health. Examination showed a large myomatous uterus with the cervix unaltered. There was no hæmorrhage, but when the sound was passed the uterine cavity bled freely. He decided to perform panhysterectomy. When the abdomen was opened, as the uterus felt peculiarly soft, it was grasped with a museaux forceps in what seemed to be the most solid part. The forceps, however, tore a hole in the surface of the uterus, and a large quantity of yellowish creamy fluid escaped. Fearing that the uterus would tear, it had been carefully packed off, so that none of this fluid got into the peritoneal sac. It proved, however, not to be pus. The removal of the uterus was easy, but scattered everywhere over the pelvis he found nodules which were deposits of carcinoma. These and the condition of the uterus showed the great extent to which the disease had extended without any symptoms. The patient did very well. He also exhibited a specimen of carcinoma of the cervix removed by Wertheim's operation. The patient was 25 years of age; married 4 years. Four months before he saw her she had a perfectly normal labour, and suffered from nothing either before or after her babe was born. She had no bleeding until six weeks before he saw her, when she described a creamy discharge, with streaks of blood. The disease in the cervix was advanced, and the specimen showed the very large amount of tissue which could be removed with the uterus by this operation. The patient made a good recovery, and was the fourth under the age of 30 for whom he had performed Wertheim's operation this year.

Sir WILLIAM SMYLY said it was very difficult to prophesy in myoma. He recalled a case in which the patient had had a uterine tumour for 30 years. Six months after seeing her it was fixed in the pelvis with malignant disease.

Professor ALFRED SMITH cited a case in which, after some hesitation as to giving advice, he dilated the uterus, and found what he thought to be a tiny ulcer. He scraped away sufficient for a microscopic examination. The pathologist pronounced it to be malignant disease, rapidly growing, in which the prognosis would be very bad. It was, however, a typically ideal case for good results, and he removed the uterus, but within nine months the patient was dead. The case brought home to him the fact that the useful information given by the pathologist could be extended to state whether the tumour was actively growing or not.

The PRESIDENT (Dr. Jellett) said the opinion given 20 years ago as to a tumour not doing harm might have been perfectly correct then, in view of the risk of operation; but now it is possible and right to advise the performance of operation on account of the great improvement in their technique.

Dr. GIBSON replied.

#### OVARIAN PREGNANCY.

Dr. E. HASTINGS TWEEDY exhibited a specimen of ovarian pregnancy, probably the first exhibited in Ireland. A. H., æt. 25; married four years; three children, last five and a-half months ago (June, 1909); one abortion. Menstruated September 18th, 1909, first and only time since delivery. November 5th.—Acute pain in right lower abdomen, from which she almost fainted. Examined at 4 p.m., November 5th, in extern department. Very tender mass the size of a hen's egg to the right of retroverted uterus. Left appendages normal. Tumour on right could not be definitely localised to ovary or tube.

*Diagnosis.*—Extra-uterine pregnancy.

November 13th, 1909.—In the interval had several attacks of pain. Morning of November 13th pain more severe, and associated with slight uterine hæmorrhage. On admission, tumour increased to twice its former size, otherwise physical examination the same.

*Operation.*—November 16th, 1909.—Ether. Right

oophorectomy. Both tubes and left ovary microscopically perfectly normal. Blood clot about 3 inches in diameter completely obscured right ovary. This was clamped and removed, ovarian tissue being cut through in removal.

The case had fulfilled all the conditions laid down for ovarian pregnancy. He thought the specimen was worth public acknowledgment by the Section.

Dr. TWEEDY also exhibited a specimen of specific elephantiasis of the vulva. M. B., æt. 30; married 14 years; last pregnancy 10 years ago; three dead-born children; one child lived two hours. Wasserman's reaction for syphilis positive. (Reported from Sir A. Wright's Laboratory.) Has always had a yellowish purulent vaginal discharge. For ten years has had a tumour of the vulva, which has grown slowly but steadily.

*Physical Examination.*—Hypertrophy of labia minora, measuring about  $2\frac{1}{2}$  by  $3\frac{1}{2}$  inches. Considerable œdema. Induration and œdema involved labia majora, and extended down to ischio-rectal fossa on either side.

*Operation.*—Excision. Interrupted catgut sutures.

Dr. ROWLETTE said the specimen of ovarian pregnancy showed to the naked eye the *corpus luteum*. A section taken through the *corpus luteum* and the edges of the blood-clot showed a proliferation of the cells of the *corpus luteum* and the mass of blood-clot in which three or four villi were seen. The other specimen consisted of lax connective tissue covered with a thin skin. The laxity was probably due to an increase of the lymphatic spaces.

The SECRETARY quoted a case reported in the November number of the *American Journal of Obstetrics*. On the day the woman expected to be delivered she complained of pains. These went off, and 12 days later she went into hospital. A tumour was found strongly resembling an ovarian cyst. On opening into it a foetus was found. This was delivered and resuscitated. The child was up to term, and free from deformities, and the patient made a complete recovery.

The PRESIDENT said the case was one in which they must suppose a person capable of making a mistake until he could conclusively prove that he had not made one. It was not a question of distrusting the powers of diagnosis of Dr. Tweedy and Dr. Rowlette, but rather a question as to whether the whole profession would accept the power of the Section to express an opinion. He, therefore, urged Dr. Tweedy to refer the specimen to a committee. His own opinion was that it was an ovarian pregnancy.

Dr. TWEEDY, in reply, said he was quite agreeable that the diagnosis should be confirmed.

Sir WILLIAM SMYLY proposed that Dr. Tweedy's specimen be sent to the Reference Committee for report.

Professor ALFRED SMITH seconded, and the motion was passed unanimously.

#### PAINLESS LABOUR.

Dr. SPENCER SHEILL reflected over the usual suffering of women in labour, and quoted three exceptions to the rule he had observed in his own practice—in one of them the process was entirely painless. He argued, "If Nature sometimes allows childbirth without pain, why should the obstetrician not endeavour to follow her good example?" He spoke of the gain to surgery of chloroform and ether, and their disadvantages in labour, at any rate in the long first stage. The expectant mother of to-day is, according to him, less able or willing than her mother or grandmother to bear bravely the suffering entailed, due largely to the evils of civilisation and to the present-day pursuits of women. For this reason he had used in his practice during the past year the scopolamin-morphin treatment on some nineteen cases, and gave his results, which he believed are the first of the kind published in Ireland. The many contradictory reports from users of it since Krönig's first paper on the subject are due, he believed, largely to great differences in the quality of the drugs used. He quoted the opinion of some who still believe in such a thing as "death from labour shock" *per se*,

and stated, if it be true, "painless labour" might be a factor in lessening maternal mortality. It is generally believed that scopolamin and hyoscin are exactly similar, and the author quotes various authorities on chemistry who support this view—among them Martindale, Binz, and even the British pharmacopœia. True, pure hyoscin and scopolamin are chemically similar, but exist in three stereoisomeric forms—viz., dextro, lævo and racemic modifications. The important point is that the "lævo" acts much the strongest on peripheral nerve endings. He believed that some writers use the word scopolamin to denote this form, and hyoscin to denote the other weaker forms. The processes of manufacture can change the stronger form into the weaker. Messrs. Burroughes Wellcome have assured the author that their "Tabloid" hyoscin hydrobromide consists only of the pure "lævo" form. Scopolamin, he stated, is also a respiratory and circulatory stimulant, and so counteracts some undesirable effects of morphia. The doses are from  $1/200$  to  $1/100$  grain of scopolamin and  $\frac{1}{4}$  to  $\frac{1}{2}$  grain of morphin. The scopolamin is sometimes repeated, the morphin seldom or never. They are used in the first stage when pains are getting strong, quietness is then insisted upon, and the room is darkened. The patient may sleep or get drowsy, but labour proceeds unaffected. Loss of memory for the time being is the principal after-effect he had noted. He had also seen flushing of the face and quickened pulse. He had not observed asphyxia neonatorum, post-partum hæmorrhage, etc., recorded by others. A case of chorea gravidarum was very favourably affected. The author believed the drug would be useful in eclampsia in counteracting the depressant action of morphia alone, and preventing the morphin from checking uterine contractions. He warned them against the use of hard water in making the solution, as alkalies will precipitate the alkaloids, and so reduce the dose given. He concluded by stating that scopolamin-morphin has many advantages, but doubted if these were not outweighed (except in a limited number of cases) by certain disadvantages; and advised more extended trial in Ireland by the large maternities.

Dr. TWEEDY said he had observed that if the vagina was tightly plugged labour progressed almost painlessly, no doubt owing to pressure on the cervical ganglia.

Dr. FREELAND said they first commenced to give scopolamin at the Rotunda in September, 1908. They now gave  $1/120$  scopolamin, with  $\frac{1}{4}$  morphia, and repeated in  $1/180$  grain doses without the morphia. They had given it in about 40 cases. One baby was born slightly asphyxiated, but it breathed after a hot bath. The others were born perfectly normal. None of the women showed any abnormalities after labour, except one who got out of bed when not watched. He thought the use of forceps had been less frequent, and he did not think it prolonged labour. The majority of the patients went asleep for an hour or two after injection, and wakened up with more or less demonstration during a pain and slept between pains. They had three absolutely painless deliveries.

Dr. SOLOMONS said that amongst other cases which he had treated by the scopolamin method was one which had occurred a few days previously. In that case he gave scopolamin hydrobromide  $1/120$  gr., and morphia sulphate  $\frac{1}{4}$  gr., when the os was three-quarters dilated. The patient had been very rowdy, but after the injection she slept, and was surprised when informed of the birth of the baby.

The PRESIDENT said he had given the drug in one case, and had obtained a painless labour. There was some hæmorrhage after delivery, and he found it was from a laceration about the vagina. This bore out Dr. Sheill's remark that women under scopolamin morphine anæsthesia, not appreciating the pain, were apt to strain very hard.

Dr. SHEILL, in reply, said he thought the plugging of the vagina only substituted one pain for another. The cases mentioned showed the disadvantages of the method, which required constant medical supervision.

## LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD DECEMBER 16TH, 1909.

The President, Mr. T. H. BICKERTON, F.R.C.S., in the Chair.

DR. J. M. HUNT showed a case of Vincent's angina, and referred to the differential diagnosis between it and diphtheria and syphilis. There were two other cases in the same family.

Dr. E. E. GLYNN demonstrated the characteristic fusiform bacilli and "spirilla" from the case, both in smears and with the dark-ground illumination.

Dr. THURSTON HOLLAND demonstrated solid carbon dioxide, the method of preparing it in the form of sticks from the cylinder of gas, and explained its uses for the removal of *nævi*, etc.

CASE OF ADAM-STOKES' DISEASE IN A CHILD, *Æt.* 5½.

Dr. HUBERT ARMSTRONG read notes of a case of heart-block occurring in a boy, *æt.* 5½. The symptoms began in July of this year, about a week after an alleged fall upon the head. At first there was severe headache, occasional delirium, temperature 104° and 105°, with pulse 48 and lower. There were no other symptoms, and the nature of this febrile attack, which lasted 5 days, is not clear.

Patient recovered, but a fortnight later had a series of epileptiform attacks, accompanied by profound syncope, and lasting over 5 days, on the second of which he was admitted to hospital. After admission he had eight convulsions in three days, and in the intervals there was great cerebral irritation, so much so that the case was regarded as one of meningitis until lumbar puncture revealed a normal c.s. fluid. This irritability disappeared 24 hours after the last "fit." The pulse rate during the first ten days varied erratically between 28 and 84. It then became constant between 50 and 60 for five days, when it rose to above 100 for four days. It then fell to between 40 and 50, and has maintained the same rate to the present. Simultaneous venous and radial pulse tracings taken during this last period show typical dissociation of auricular and ventricular rhythms, the auricles beating about 70 when the ventricular rate was 45. The phenomenon was also demonstrated on the fluorescent screen.

There have been no further epileptic fits since the third day after admission, and the child, except for a little cyanosis, and that he is incapable of much exertion, at present appears quite comfortable. There is a slight mitral regurgitant murmur, but the cause of the heart block is undetermined.

Dr. JOHN HAY read a paper on

## HEART BLOCK, COMPLETE AND PARTIAL,

in which he referred to six cases of Adams-Stokes' disease which had been under his supervision during the last two years. Five of these cases were of the arterio-sclerotic type, the sixth was apparently caused by a severe gonococcal infection in a young woman. The patients exhibited all the grades of severity, ranging from slight attacks of vertigo and transient blurring of consciousness, with bradycardia, to grave syncope and epileptic seizures. The insidious onset of the malady was referred to, diminution in the area of cardiac response being in some instances the first disturbing feature. Records were shown demonstrating the actual transition from partial to complete block, and the return from complete to a two to one rhythm without the appearance of any subjective symptoms. The pathological findings in the disease were referred to, and treatment was considered. One of the cases had been greatly benefited by potassium iodide, and the gonococcal case had improved after the exhibition of a gonococcal vaccine.

The case and paper were discussed by the President, Drs. Macafee, T. R. Glynn, Sir James Barr, Drs. Abram, T. R. Bradshaw and Buchanan, and Dr. Hay replied.

## CORRESPONDENCE.

## FROM OUR SPECIAL CORRESPONDENTS ABROAD.

## GERMANY.

Berlin, Dec. 26th, 1909.

AT the Medical Society a discussion took place on the subject of

## TREATMENT BY TUBERCULIN,

introduced by Hrn. Citron.

Hr. Jochmann said he agreed with the introducer of the subject as regarded intervals, gradually creeping up from small doses, and avoidance of fever reaction; but he did not agree that there was no biological criterion for estimating the effects of treatment. The cutaneous reaction was such a criterion. In his patients he brought about a cutaneous reaction both with "old" tuberculin and tuberculin emulsion, before commencing actual treatment. Tuberculosis, as a rule, reacted to both preparations. If now a patient was immunised with "old" tuberculin when the immunisation had reached a certain height, the reaction to it ceased, but not to the bacillus preparation; such a dose should only be reached with "old" tuberculin. To this treatment was added a continuation with the emulsion as far as the disappearance of the cutaneous reaction with this preparation also. For the latter, stronger emulsions of bacilli were required than were in the market; the speaker took a dilution of the dry substance of 1 in 50. With disappearance of the cutaneous reaction for both preparations he considered that a considerable degree of immunity had been reached.

Out of 12 cases treated by himself with the "sensibilised" tuberculin, 9 of them became feverish with a dose of 1/1,000. As regarded the improvement mentioned, it took place also with the ordinary tuberculin emulsion, so that there was no need of a new preparation.

More importance was to be attributed to the occurrence of antibodies. In treatment with "new" tuberculin at a certain height of immunisation, antibodies were regularly seen to occur which remained longer in the blood than with "old" tuberculin. From Citron's communication, it would appear that with "sensibilised" tuberculin these antibodies only rarely made their appearance, which was evidence in favour of the old emulsion. According to all recent experiences—for example, in case of meningococci also—the amount of complement-forming material went parallel with that of the protective substance.

Hr. Fr. Meyer remarked that serum treatment was often prohibited on account of over-sensitiveness on the part of the patient. He had had a serum prepared from a combination of sensibilised bacillus emulsion and tuberculous serum from tuberculous animals. When applied to the human subject the smallest doses were to be given at first, gradually increasing them. No local reaction had ever been observed with this new serum. Cases suitable for it were patients without fever, and initial and local tubercloses. It should not be used with cases that had been treated with "old" tuberculin, as a condition of over-sensitiveness was set up in patients treated by it.

Hr. Eckert said that in Heubner's Klinik only scrofulous cases were now treated by tuberculin. The general condition of the children improved considerably under the treatment, but how much of this improvement was due to stay in hospital it was difficult to say.

Hr. Max Wolff said that the dangers of tuberculin treatment prevented many medical men from making use of it. But, with sufficient experience with tuberculin methods, these dangers could be avoided. Very small doses should be begun with. As regarded the question of the preparation, judging from recent experiences it was not what preparation, but how it was used. He had used the "old" tuberculin principally. The bacterium emulsion, from his own experiences, did not reduce the fever. The most suitable

cases for tuberculin treatment were catarrhal attacks, but even with solid infiltrations he had repeatedly seen surprising results. Failures were not wanting, however. Tuberculin treatment could also be carried out with out-patients.

Hr. Ed. Meyer had seen good results with Fr. Meyer's serum in tuberculosis of the larynx—better than with the "old" tuberculin.

Hr. S. Cohen said that at the Finkelstein Klinik three children treated with Meyer's serum had improved. That the curative action of tuberculin depended on its immunising properties was not proved, as in a large number of children their sensitiveness to tuberculin increased under treatment, although they improved under it.

Hr. Max Schultz had seen improvement under the treatment in cases of active disease. He had also used the sensibilised serum, and had obtained results similar to those obtained with "old" tuberculin; perhaps the fever was less.

Hr. F. Kraus said we could not draw conclusions as to efficacy of treatment from the formation of antibodies. We could not depend on individual symptoms. We must take the case as a whole. In any case, tuberculin treatment must be taken up again, and generally by the practitioner—not in hospitals alone.

Hr. Citron, in reply, said that the good results could not be doubted, and that the "Neutuberculin" was to be preferred. As required by Jochmann, he had made control experiments, and found that the "sensibilised" emulsion acted more mildly in regard to local infection, and more rarely set up fever. The disappearance of the Pirquet reaction was not a biological test.

## AUSTRIA.

Vienna, Dec. 26th, 1909.

### EPIDEMIC POLIOMYELITIS.

At the Gesellschaft der Medizin, Zappert gave a historical report of an epidemic in Vienna and Lower Austria between July, 1908, and February, 1909. The cases recorded are 290, but 266 may be taken as genuine. Of these 266, 129 came from Vienna, and 137 from the lower portion of Austria. The greatest number attacked were between the first and third year of life. Poverty and density of population could not be said to play any particular part in the epidemic. According to recognised semeiology, the 266 cases comprised 241 with spinal symptoms, viz., paralysis of the limbs, the greater number being on the left side, as well as paralysis of the muscles, back, neck, and abdomen, with transitory conditions of the respiratory muscles. The second form, or Landry's paralysis, which consisted of ascending or descending paralysis, with a fatal ending on the respiratory centres, were 14. These mostly took place in the older children, and ran their course in a few days. The third form comprised pontine and bulbar paralysis, attacking 25 of the cases, involving ocular, facial, and constrictor muscles. One of these cases included a cerebral condition. The fourth class included the encephaloid form, affecting the hemisphere of the brain and manifesting itself by spastic unilateral paralysis. In one of the post-mortems of this case changes were observed in the cortex as well as the ganglia of the cord. The ataxic form of Wickmann may be described as an abortive form of ataxia, while his sixth, or polyneuritic form, has no definite anatomical symptom beyond pain or tenderness on pressure of any of the nerves, associated with hyperæsthesia. The seventh and eighth forms of the same author may be viewed as an abortive form of meningitis. Many of these meningeal cases recover very quickly, and may be considered more of an influenza character, with an acute form of visceral catarrh. Other cases, however, went as rapidly down and died before anything could be done. In all the forms mentioned above there was a prodromal state in which fever, malaise, sleeplessness, or somnolence, with angina or other gastric disturbances were present. Frequently the meningitis was the most prominent symptom at first, followed by the paralysis, which in a few days would reach the

maximum, then subside and gradually recede. In a few of the cases great pain in the extremities, neck and head appeared as sequelæ. The fever was never specially high in many of the cases, and seldom lasted over a week, when the paralysis would appear.

Out of the 266 cases, 29, or 10.8 per cent., died, recovery in 37, or 13.8 per cent., was announced, while the remaining cases had a partial recovery. The deaths in Landry's paralysis usually terminated in severe meningeal symptoms, diarrhœa, or pneumonia.

The attacks in Vienna were somewhat irregularly distributed over the city, but the west or northern portions were severely attacked, while the south and east were very little affected. Grouping in particular houses could sometimes be declared, but it could never be definitely established that a particular centre was the cause of the infection. The epidemic, however, appears to have confined itself to limited radii, but the attacks of sisters and neighbours cannot be conclusively proved to establish the disease as infectious, although we must admit it is endemic in Vienna, and suddenly burst forth as an epidemic, as we have seen, at the early part of the year, with its greatest incidence in the early summer months.

## HUNGARY.

Budapest, Dec. 26th, 1909.

### SPONTANEOUS CURE OF AN ANEURYSM.

At the Biharmegye Medical Society, Dr. Révész exhibited a preparation of an aneurysm of the arch of the aorta which had undergone natural cure. B. F., æt. 41, was admitted into the hospital, under Mr. Révész's care, on November 24th, suffering from fracture of several ribs on the left side, with traumatic pleurisy and hæmothorax. On the 27th he died. At the post-mortem examination a tumour about the size of a walnut was found attached to the right side of the ascending portion of the arch of the aorta. When cut into, this tumour was discovered to be an aneurysmal sac filled with laminated fibrine, and having a small cavity communicating with the arch. The left innominate vein was entirely obliterated, and, in the form of a fibrous cord, crossed the lower part of the tumour. The arteries springing from the transverse portion of the arch were normal. No history could be obtained that this man had at any time suffered any inconvenience from the presence of the aneurysm.

At the Sixteenth International Medical Congress, Dr. Grossmann read a paper on

### NASAL ASTHMA.

He said that experimental researches undertaken in the hope of explaining the phenomena of nasal asthma proved that electrical or mechanical irritation of the nasal mucous membrane led to a notable disturbance of the cardiac function, followed by a considerable engorgement of blood in the pulmonary circulation, and by an increase in the external dimensions of the lung. In curarised animals this increased volume of the lung caused a rise of pressure in the inter-thoracic space and a depression of the diaphragm. This effect of nasal irritation was completely absent if either the second branch of the trigeminal nerve or the two vagus nerves were previously divided. There was, therefore, reflex action in a curved path the centripetal portion of which was formed by the vagus nerve. This enlargement of the lung was not caused exclusively by the accumulation of blood, but also by the fact that the pulmonary capacity—i.e., the available pulmonary area—increased in direct proportion to the engorgement with blood. The lung became larger, not only as regards its external dimensions, but also as regards its intra-pulmonary capacity. In accordance herewith the intra-pulmonary pressure, unlike the pressure in the intra-thoracic space, fell when the pulmonary circulation was engorged with blood. This enlargement of the lung was accompanied by rigidity, which seriously interfered with respiration.

### TYPHOID OUTBREAK IN NAGYVÁRAD.

Nagyvárad, one of the most flourishing provincia!

towns of Hungary, became the very nest of a typhoid epidemic lately. The severity of the danger can be estimated from the relatively too high percentage of cases notified. Nominally, since August 1st this year, more than 300 cases were attended by medical men in the town, and about 200 were kept in hospitals. The mortality rate was about 1 in 1,000, taking 58,000 as the number of inhabitants. The cases are mostly of the severer type, perforation of the bowels being very frequent. The town magistrates have strictly investigated the cause of the extraordinary spread of the disease, and they succeeded in ascertaining the fact that the source of the infection came from a neighbouring village, which supplied contaminated milk to a certain part of the town's population, where the disease was, in fact, most notable. Although the members of the Board of Health are taking every precaution and enforcing preventive arrangements for controlling the spread of the disease, no decrease in the number of fresh infections is observed yet.

A remarkable feature of this epidemic is that the sanitary inspectors of the town have resolved to establish a so-called "controlling station for late typhoid patients." This station will examine from time to time persons who have suffered from typhoid for typhoid bacilli, in accordance with the new experiences of some German authors, who state that after a typhoid attack a person, called "bacilli carrier," may carry in himself, and chiefly in his gall-bladder and bowels, typhoid bacilli for twenty years. Such persons, they say, evacuate typhoid bacilli, and thus they are capable of infecting others, if they are not taught how to defend their neighbours from infection. Here, at this station, they will be instructed how to disinfect their stools, which they have to do as long as the blood examination will reveal the presence of typhoid bacilli.

### FROM OUR SPECIAL CORRESPONDENTS AT HOME.

#### GLASGOW.

#### INTERNATIONAL INTERCHANGE OF STUDENTS.

PRINCIPAL SIR DONALD MACALISTER presided at a meeting held in the Students' Union on the 13th inst., in the interests of the International Interchange of Students (United Kingdom Section), when Mr. Henry W. Crees, the hon. secretary of the movement, addressed the meeting. Principal MacAlister explained that the idea underlying the scheme was that no single University was quite sufficient in itself, in so far as giving its students the full advantage of the knowledge of other places was concerned, and that it was desirable, in the interests of the broader education of students, that they should have an opportunity of making each other's acquaintance. By personal contact with other parts of the Empire and other countries a great deal of additional knowledge could be obtained, and if some arrangement could be made for the University of Glasgow by which chosen students were able to be sent as missionaries to other parts of the Empire, and return with their student's mind full of what they have seen, and impart the information they had obtained to their fellow undergraduates before the end of the academic course, it was conceived by those who had put forward the scheme that great advantage would be obtained.

Mr. Crees, in explaining the scheme, said that the first essential was that the students had to return to their own University for a time, in order that their widened outlook of ideas might be shared, as far as possible, by their contemporaries in their college life. It was hoped that fourteen, or more, scholarships would be available for use in certain Universities of the United Kingdom annually, and ten scholarships in the United States, and four in Canada. The qualifications for these scholarships would be along the lines of the Rhodes scholarships, and it was intended that the holders of these scholarships would view, as far as possible, the various activities of the countries

visited, both in educational, social, administrative, and industrial matters, while this should not interfere with the academic course of the student at his own University.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### THE ETHICS OF ANTI-VACCINATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The enclosed card may remind you that for many years I was a leading specialist practising in London among the wealthier classes, and that I now occupy a position of complete detachment from professional life. Perhaps you may excuse me, under these circumstances, for preferring to veil my personality under a *nom de plume*. I write to confirm the statement made in your excellent editorial note under the above heading to-day, December 22nd, to the effect that every form of quackery has derived an enormous stimulus during late years from the anti-scientific propaganda which involves disparagement of the art of medicine and of its votaries. A large section of fashionable and wealthy people are neither intellectual nor intelligent, and have derived no advantage from so-called education. The home influence predominates, and this is mostly on the side of frivolity and scorn of all serious knowledge. In after life reading is confined to trashy novels and society papers such as those to which honourable gentlemen of the kind you have criticised are the chief contributors. Towards middle age the ailments of these people begin. The wives, with few and neglected, if any, children, finding fatigue and dissatisfaction beginning to make their mark on their faces, seek the help of the beauty doctor to restore their complexion, remove their wrinkles, and save their falling hair. The beauty doctor, who spends thousands a year in advertisements in society papers, is in many cases merely a blackmailer, and plunders with impunity, well knowing that no victim will dare proceed against him and expose her folly in a law court. These fashionable women would resent being told that their face is merely the index of their bodily state, due to their mode of life, and that their only salvation in health would be in following the advice of a wise physician, and they look upon doctors as heartless fee-hunters. This feeling sends them and their husbands straight into the hands of the quacks when organic failure in one or other direction begins to trouble them, or when, becoming worn out and weary in the unchanging pursuit of pleasure, neurotic symptoms begin to develop. This class of patient, as a rule, does not go in for Christian Science; this catches rather the "religious" subject. The smart people go to even a lower class of thaumaturgists—those whose signs decorate the fronts of such an amazing number of buildings in certain fashionable quarters. It is all a question of advertising. Two of the men who are doing the biggest trade at the present moment followed for some years the profession of acrobats. They now cure every functional and organic disease by "electric" baths in which the electricity is negligible; by manipulating the joints of the toes by methods of which they alone possess the secret, and by other procedures having an equally scientific justification. They are spending many thousands a year in advertisements, a measure of their gains, and their puffs are not only to be found in society journals, whose editors, perhaps, know no better, but in the pages of leading papers, whose editors and proprietors are fully aware of the nature of the traffic from which they are indirectly deriving income.

I am, Sir, yours truly,

SENEX.

Near Reigate, Surrey, December 22nd, 1909.

# THE STANDARDISATION OF DISINFECTANTS. *To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—Notwithstanding the large amount of chemical and bacteriological work the *Lancet* Commissioners have done, their report does not mark any fundamental advancement in respect of what was previously known concerning this subject.

They have apparently recognised the impossibility of determining the disinfectant value of perchloride of mercury, chloride of lime, and formalin by the bacteriological test which they describe, and yet they have examined "Sanitas Fluid" by it, and classified it as a coal tar disinfectant, although that liquid contains no coal tar, and is quite as dissimilar in character from coal tar preparations as are the three other articles above named.

In regard to coal tar disinfectants generally, serious objection is to be taken against the chemical part of the investigation, inasmuch as the process employed to determine the percentage of active principles fails to give satisfactory results. By way of proof, the *Lancet* process has been employed in our laboratories in respect of a mixture known to contain 88 per cent. phenoloids, but it only showed the percentage of 60 per cent., whereas in respect of a disinfectant liquid known to contain 52 per cent., Mr. Wynter Blyth's acetone process showed it to contain 54 per cent., a much more satisfactory result, while the *Lancet* process gave only 34 per cent.

As for the bacteriological test which has been made, it simply gives the relative values of the coal tar disinfectants which were subjected to examination in respect of *B. coli*, under the special circumstances observed; just as the standardised *B. typhosus* (Rideal-Walker) test gives relative values in respect of *B. typhosus* under the special conditions observed in that test. In neither case do the results indicate the real disinfectant values of the preparations, nor reproduce the conditions under which disinfection has to be carried out in practice by the medical profession and the public at large. This seems to be recognised by the Commissioners themselves, for they state that "the conditions of the test are (so) far removed from those of natural disinfection."

According to the results obtained by the Commissioners, "Sanitas-Bactox" ranks, amongst the homogeneous liquids which were tested, equally with one other preparation, as the highest in germicidal power, on the one hand, and takes top place when the cost is compared on a basis of efficiency. When, however, it is examined by the Rideal-Walker test it gives a co-efficiency of 20 at least, whereas the said other disinfectant only reveals a co-efficiency of about 15. Again, "Sanitas-Okol" takes first place amongst coal tar disinfectants of the emulsion order, both in respect to co-efficiency and comparative cost.

The *Lancet* Commissioners have altogether disregarded the valuable inhibitive and antiseptic properties of the various other disinfectants, and no attention has been paid to their behaviour as oxidising agents or to their chemical activities. They have also disregarded altogether the matter of environment. Every student who has paid the most cursory attention to the subject knows perfectly well that disease is not produced by the mere mechanical presence of micro-organisms, but by their production through chemical reactions of definite poisonous substances, and it is these poisonous substances that constitute the true infectants of disease, and not the microbes themselves. Practical disinfection, therefore, aims at preventing the formation of such infective material, on the one hand, and of destroying it, if and when produced, on the other hand, and is not confined to the mere destruction of universally distributed micro-organisms which, in their proper sphere and under proper control, constitute one of the most beneficent orders of creation.

Germicidal value, therefore, is no measure of disinfectant value; removal by washing (cleanliness) is really much more efficacious, up to a point, than destruction of microbic life by the application of germicides, so that rarely is the use of strong germicides called for, at any rate, at the hands of the

public, and "Sanitas Fluid" is for most of such uses more than sufficiently strong, and may often, indeed, be diluted with several times its own quantity of water before use.

The only measure of utility of any disinfectant that is offered for public use is the extent to which it may be satisfactorily employed for the purposes for which it is advocated, and the *Lancet* Commissioners have not made any serious attempt to grapple with the problem from this, the only rational standpoint.

I am, Sir, yours truly,

C. T. KINGZETT, F.I.C., F.C.S.

Ex-Vice-President, Society of Public Analysts.

London, December 24th, 1909.

## OBITUARY.

BENJAMIN SAVAGE ROBINS, M.R.C.S.ENG., L.S.A.

WE regret to hear of the death of a well-known Midland practitioner. Mr. B. S. Robins, of Grantham Road, Sparkbrook, died on Sunday, December 19th, in his 78th year, and Birmingham thereby loses one of its oldest medical practitioners. As far back as 1849 he was articled to the General Hospital, under the late Mr. Oliver Pemberton, and was for a time House Surgeon, later occupying a similar position at the Wolverhampton Hospital. Mr. Robins subsequently joined Mr. John Archer, of Deritend, in partnership. For many years the deceased was Medical and Vaccination Officer for the Ashton Union, and for about forty years was a Certifying Surgeon under the Factory Acts, a position he held at the time of his death, which occurred from heart failure following an illness extending over two or three years. Mr. Robins was the oldest surviving member of the Union Club, having been elected in 1858. He took no part in political affairs, but was well-known in social circles. The deceased gentleman was the second son of Mr. John Robins, of Dunsley Hall, Kinver, and married a daughter of Mr. Arthur Dabbs, of Seckington, near Tamworth. He is survived by three sons and two daughters.

## REVIEWS OF BOOKS.

### MYOMATA OF THE UTERUS. (a)

THIS very fine monograph on a most important subject is a companion volume to Dr. Cullen's well-known works on Cancer of the Uterus, and on Adenomyoma of the Uterus. The book consists of some 35 chapters, and, in them, the subject under consideration has been discussed from every conceivable standpoint. To give a proof of Dr. Cullen's breadth of treatment it is only necessary to enumerate the titles of a few of the chapters:—Parasitic uterine myomata; dilatation of the uterine lymphatics associated with myomata; lipomyoma of the uterus; myosarcoma of the uterus; the condition of the uterine mucosa in cases of myoma; conditions found in the ligaments passing to or from the uterus in cases of myoma; the bladder in cases of myoma; the ureters in cases of myoma; analysis of the cases of uterine myomata found at autopsy in the pathological laboratory of the Johns Hopkins Hospital from the opening of the hospital to July 1st, 1906; pregnancy and uterine myomata; results of operations for uterine myomata.

By parasitic uterine myomata, the authors mean myomata that have for some reason become detached partially or almost completely from the uterus, and which receive their blood-supply from another source than the uterine vessels. The commonest source of the blood-supply of these parasites is the

(a) "Myomata of the Uterus." By Howard Kelly, Professor of Gynecology in the Johns Hopkins University, and Thomas S. Cullen, Associate Professor of Gynecology, Johns Hopkins University. Pp. xix. and 723. Philadelphia: W. B. Saunders Company. 1909.

omentum, and Dr. Cullen notes that in such cases there is, as a rule, a marked disappearance of the omental fat. There are also illustrations of myomata which received their nourishment from the rectum and from the mesentery of the small intestine, from the bladder and from the abdominal wall.

The different chapters dealing with the degenerations and changes in myomata are most interesting, and their illustrations are especially valuable. We cannot find, however, any reference to so-called "red degeneration." The term does not appear in the index, nor can we find any other term which might include it.

In the chapter on the symptoms associated with uterine myomata, there are some very interesting tables dealing with the fertility of women who develop such tumours. It appears that out of 1,149 cases of myomata, 842 of the patients were married, and 307 were single; 548 were sterile, 75 had had miscarriages, and 490 had borne children, prior to the operation. It thus appears that, of the married patients, 277 out of 842 were sterile. Dr. Cullen does not discuss the cause of this sterility, except to say that "we are still unable to say with any degree of certainty that the myoma *per se* was the direct cause of the sterility." We have said enough of the subject matter of the book to show what a valuable contribution it is to medical literature. Its illustrations are unsurpassed, and are in themselves a veritable atlas. We congratulate Dr. Cullen on his work, and Dr. Howard Kelly on his association with it.

#### ALLBUTT AND ROLLESTON'S SYSTEM OF MEDICINE (a)

THE present volume of Sir Clifford Allbutt's System of Medicine deals with the diseases of the heart and blood vessels. In the former edition its contents formed part of Volume V. and part of Volume VI. It thus has the advantage over its predecessor that it provides its readers with the diseases of the heart complete in a single volume instead of spread over two volumes and associated with other subjects. Considerable changes have been made in the different articles. The opening chapter dealing with the "Physics of the Circulation," which was originally written by Professor Sherrington, has been revised by Dr. James Mackenzie, who has added to it an account of the peripheral circulation, including arterial blood pressure. A new article on Stokes-Adams disease has been contributed by Professor Osler and Dr. Keith, while the article on over-stress of the heart has been re-written and contains a section by Dr. R. W. Mitchell—the outcome of his special opportunities of watching University athletes. The chapters on simple acute endocarditis and on the Diseases of the Mitral Valve have been re-written by Dr. Gibson. The account of functional disorders of the heart has been re-written and a new article has been added on Aneurysm, by Professor Osler.

The book is divided into two parts, the first of which deals with Diseases of the Heart, and the second, with Diseases of the Blood-vessels and Lymphatics. There are 85 illustrations, some of which are printed in colours, and three coloured plates. The references at the end of the chapters are very full, and have been corrected and brought up to date.

THE LORD MAYOR, on December 20th, re-opened the Metropolitan Hospital, on completion of the various structural alterations and improvements, which have necessitated the closing of the wards during the last few months. The total expenditure has been some £12,500, of which about one-fifth still remains to be collected.

(a) "A System of Medicine by many Writers." Edited by Sir Clifford Allbutt, K.C.B., M.D., F.R.C.P., Regius Professor of Physic in the University of Cambridge, and Humphry Davy Rolleston, M.D., F.R.C.P., Senior Physician to St. George's Hospital. Volume VI.—Diseases of the Heart and Blood-vessels. Pp. xiv. and 861. London: Macmillan and Co. 1909.

#### IMPROVEMENTS IN MEDICAL APPLIANCES.

AN interesting copy of report dated September 17th, 1909, has reached us concerning the British Antarctic Expedition, 1907-9, which was furnished with a very complete medical equipment by Messrs. Burroughs Wellcome and Co., consisting of "Soloid" and "Tabloid" preparations, which are the only forms that can be conveniently carried and preserved under such conditions. "The Congo Cases," runs the report, "were always used when at our base, and both the party of three who reached the South Magnetic Pole, and the party under Lieut. Shackleton, who attained a point 97 miles from the Geographical South Pole, carried a brown leather 'Tabloid' case, and all the 'Tabloid' products that remain are now in as good condition as when first handed over to my care two years ago. The *Nimrod* was also supplied with 'Tabloid' cases and equipment. The packets of compressed dressings were in an extremely convenient form, and the 'Tabloid' photographic outfit proved entirely satisfactory."

The following is an illustration of the "Tabloid" medicine case carried "Farthest South" by Lieut. Shackleton.

This was taken with the party of six that made the ascent of Mount Erebus, 13,350ft., and used on southern journey under Lieut. Shackleton, October 28th, 1908—March 4th, 1909. Latitude 88° 23' S. Longitude 162° E. Distance covered in this journey, 1,728 statute miles. Medicines quite satisfactory. The report is signed by E. P. Marshall, M.R.C.S., L.R.C.P., Surgeon to the British Antarctic Expedition, 1907.

#### ROGERS' KLORAM INHALER.

WE have received from Mr. Frank A. Rogers, of 327 Oxford Street, London, W., a new chloride of ammonia inhaler. We have tested this apparatus carefully and have no hesitation in saying it is one of the most compact and workmanlike appliances of the kind that has hitherto come under our notice. The method

is simplicity itself, and the inhaler, besides being convenient to use, contains few working parts, and is not likely to get out of order. The price is moderate, as the whole apparatus, with materials for a prolonged course of treatment, is supplied at 7s. 6d. A good idea of this compact inhaler can be obtained from the accompanying illustration.

## SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

*Specially compiled for THE MEDICAL PRESS AND CIRCULAR.*

**Advantage of the Combined Intra- and Extra-peritoneal Uretero-lithotomy for the Removal of Stones from the Lower Ureter.**—Jonas (*Amer. Journ. of Obs.*, LX, 5). There are three locations in the ureter where a stone is liable to be arrested: (1) An inch and a-half to two inches from the pelvis of the kidney as the ureter bends over the psoas muscle; (2) in the bend of the ureter one to two inches below the basis of the pelvis; (3) in the vesical portion. The usual operation for stone in the vesical portion is intra-vesically. When the stone is situated an inch or more from the bladder wall this method is not safe, and the combined intra- and extra-peritoneal method is recommended. Ureter stones lodged near the pelvis of the kidney are best removed extra-peritoneally through the incisions as used for exploring the kidney. The danger of urinary fistula from incision of the ureter is extremely slight if the passage to the bladder is free. Direct drainage of the pelvis of the kidney is preferable, since we believe that most ureter stones originate in the kidney pelvis this should be drained in almost all cases, even though the conditions for natural drainage are favourable. We possibly underestimate the frequency of primary ureter stones since in the majority of cases only one stone is found. The operation must aim (1) to remove the stones, and (2) to prevent the recurrence. The proper treatment for stones in the lower ureter is a laparotomy which allows a thorough examination into possible causes for the lodging of the stone, or for the origin of the stone *in situ*, removal of the cause, adhesions, twists, etc., if found intra-peritoneally, and then removal of the stone extra-peritoneally. F.

**Ovarian Pregnancy at Term, with Recovery of Mother and Child.**—Kirchner (*Amer. Journ. Obst.*, LX, 5). The patient entered hospital believing she was pregnant and beyond term. She expected to be confined on November 15th, and on this day she began to have pains. Twelve days later the patient came to hospital. The abdomen was enlarged as in pregnancy but asymmetrically, the left side being fuller than the right. Fœtal heart sounds were easily heard, loudest to the left and below umbilicus. A long median incision was made, there were numerous omental and intestinal adhesions. The mass when it was cleared resembled an ovarian cyst, and when opened revealed a fœtus. The incision went through the placenta. The child was easily resuscitated. The sac was shelled free from the abdominal cavity; it originated from the right side in the region of the ovary, and here the main blood supply was obtained. The patient ultimately made a good recovery. The left ovary and tube were normal. The right ovary was not found; the right tube was firmly adherent externally to the sac, but otherwise normal. The character of the sac is that of an ovarian cyst, and gave microscopical evidence of ovarian structure. F.

**The New Point in Diagnosis between Appendicitis and Tubal Disease.**—Morris (*Amer. Journ. of Obst.*, LX, 5). The writer points out that about an inch and a-half to the right of the navel close to the spinal column we find the right group of lumbar ganglia. Hypersensitiveness on deep pressure at this point seems to indicate that the appendix alone is affected. When the left group of ganglia is hypersensitive it points to pelvic inflammation. F.

**Considerations on the Statics of the Pelvic Viscera and their Relationship to the Operative Treatment of Utero-Vaginal Prolapse.**—Cassalis (*Journ. Obs. and Gyn. Brit. Emp.*, XVI, 5), having considered the anatomical aspect in the preceding part of the journal, says,

when a uterus is permanently retroflexed or retroverted but still mobile, it cannot be restored to anteversion and maintained so, unless some means is found of altering the stretched ligamentary attachment. Shortening of the round or utero-sacral ligaments is the operation based on the soundest principles. Gilliam's operation has an advantage over Alexander's in that it attaches the round ligament at its strongest place to the abdominal wall, but unfortunately divides the pelvis into three segments liable to cause incarceration of the bowel. This accident happened in a case with the author. Uterine retro-deviations, when the uterus is enlarged and heavy and the perivascular sheaths overstretched, require something more than a mere suspension. Descensus there or partial prolapse exactly defines this variety, as it only implies a giving way of the upper pelvic segment. These are the cases in which a well-fitting Hodge when the pelvic floor is complete gives so great relief, but one also where operative treatment, when mechanical aids have ceased to be of use, is difficult, and frequently unsuccessful. The reason is that the organ, although anteverted, has not gained its normal plane in the pelvis. Ventro-fixation is the operation best suited to these cases, and if it is contra-indicated for women still in the child-bearing period of life, it is the operation *par excellence* of the post-menopause period. Relaxation of both upper and lower pelvis planes gives rise to prolapsus uteri. The author has for some years adopted a modified Lawson-Tait's operation combined with a myorrhaphy of the levator ani, and this in severe cases combined with a solid ventro-fixation is almost always curative. He has never seen a case return with a relapse. F.

**Post-Operative Psychosis.**—Kelly (*Surg. Gyn. and Obst.*, IX, 5). The author records 40 cases, and excludes all except definite mental aberrations and cases where delirium might be due to infection, intoxication, drug, or drink habit. The psychoses seem as common after mild as after severe operations; seven were after simple repair of the perinæum. In only 12 out of the 40 cases was double oöphorectomy performed. The author does not deny that there may be some mental instability in most instances, yet is convinced that a perfectly sound individual may develop a post-operative psychosis. The insanity does not conform to any one type, the most common is acute hallucinatory confusional insanity, and this is the type found in absence of predisposition to another type. There are marked delusions and hallucinations, a distinct confusion of the intellect, and great motor excitement at times. The majority begin showing symptoms between the second and tenth days. Eight of the forty started almost immediately after the operation. The duration is variable, the shortest period in the series was two weeks, advancing from that to permanent insanity. To avoid the complication it is advised to postpone operation if possible until the patient is better disposed to it if she is showing great fear of the operation, is convinced she will die, not sleeping well, showing unusual nervous symptoms, and particularly in presence of bad family history. F.

**The Use of Scopolamine-Morphine.**—Thomson and Cottrell (*Edinburgh Medical Journal*, December, 1909) publish the results of an experience of 180 cases, in which scopolamine and morphine were used as adjuncts to a general anæsthetic. Two methods of administration were employed:—(1) An injection of 1/64th gr. of scopolamine bromohydrate with 1/6th gr. morphine sulphate two hours before the operation: (2) three successive doses of 1/120 gr. scopolamine, with 1/4th gr. morphine, given 2½, 1½, and ½ hour

before operation. The latter method was used in most of the cases, and was, we take it, that approved by the authors. The first injection generally put the patient to sleep, and the second could be given without disturbing him. In many cases general anæsthesia was induced without arousing him. For most operations a light general anæsthesia was sufficient, though in abdominal operations deep anæsthesia was advisable. In cases where struggling occurred, the patient retained no memory of pain. No attempt was made to dispense with the general anæsthetic, and chloroform was commonly employed. The authors conclude that the administration of scopolamine does away with preliminary fear, and therefore adds to the safety of the operation. The quantity of general anæsthetic required is diminished. Moreover, mucous secretion is lessened, and the task of the anæsthetist thereby lightened. There is but little sickness after operation, and the prolonged sleep spares the patient much pain and discomfort. R.

**Passage of Bacteria through Wall of Strangulated Intestine.**—Ikonnikoff (*Annales de l'Institut Pasteur*, November 25th, 1909) reports interesting observations on the passage of microbes through the wall of the intestine in cases of experimental strangulation. The strangulation was produced by slipping two or three centimetres of gut through a sterilised rubber ring of five millimetres diameter. The observer found that the passage of bacteria through the wall was related to the phenomena of necrosis, together with desquamation of the lining epithelium. Moreover, the rapidity of the passage of bacteria depended on the degree of necrosis. The organisms most commonly found were those anaerobes, which digest albuminoid material, while the *bacillus coli* and cocci were only found where the necrosis of the tissues was very intense. R.

## MEDICAL NEWS IN BRIEF.

### National University of Ireland.

At a meeting of the Senate, held on December 22nd, 1909, it was unanimously agreed that provision should be made by the University for holding the examinations for all degrees of the University for students of University College, Dublin, in University College, Dublin, and for students of University College, Cork, in University College, Cork.

It was ordered that advertisements be issued for Extern Examiners for the subjects of the medical examinations for the year 1910.

A Committee was appointed for drafting such regulations as are contemplated by the Charter and Statute A of the University.

Tuesday, April 5th, 1910, was fixed as the date at which the Spring Medical Examinations of the University will begin.

### Society of Tropical Medicine and Hygiene.

At a meeting of this society, held last week, the following resolutions were unanimously passed:—"That this society, recognising the great services rendered by Sir Alfred Jones, K.C.M.G., to tropical medicine, desires to record its appreciation of these services and sense of loss in his death. Further, that the secretaries be instructed to communicate this resolution to Sir Alfred Jones's family and to convey to them the sympathy of the society in their bereavement." "That the President be requested, on behalf of the Fellows of this society, to convey to Mr. Otto Beit their high appreciation of the great benefit which he has conferred on the study of disease, including tropical disease, by his munificent grant for the endowment of research."

### The Health of London.

DR. COLLINGRIDGE, Medical Officer of Health, has reported to the City Corporation that in the last three weeks the death-rate in the City was 16.2 per 1,000,

as compared with 15.8 in the 76 great towns of England and Wales. The City birth-rate was 10.5, as compared with 23.4 elsewhere. Eight cases of infectious disease were reported, and 14 notifications of pulmonary tuberculosis were received. Of 571 houses visited, 13 were in an insanitary condition. Nearly four tons of unsound tinned food were destroyed at wharves. Of 118 dairies and milkshops visited, all were found in a satisfactory state of cleanliness. Thirty samples of food and drugs had been examined by the analyst, and two of them (milk) were adulterated. At the markets and slaughter-houses 46 tons of meat—of which 16 tons were frozen—were condemned and destroyed. The inspection of Chinese pork continued. Of 3,861 carcasses dealt with, 286 had been condemned. At the mortuary 28,485 articles of clothing had been disinfected, and 11 inquests held.

### The Medical Care of Immigrants.

OWING to the refusal of certain steamship companies operating between New York and Europe to be responsible for the hospital bills of sick immigrants, the United States Commissioner of Immigration has notified the companies that the Government will not be responsible, and it is affirmed that the action of the companies will result in increased deportations, as none will be permitted to land from any ocean steamer until after examination by the ship's surgeon.

### Royal Army Medical Corps.

CAPT. A. E. F. HASTINGS has been detailed as Medical Officer of the first and second camps of artillery training at Bargarh. Lieut.-Col. H. W. Austen has been granted leave of absence from the 23rd inst. to January 21st. Major A. H. Morris has been granted leave of absence from the 28th inst. to February 26th, with permission to travel in France and Switzerland. Major B. H. Scott has been granted leave of absence from January 1st to February 28th.

### The Volunteer Medical Service.

It has been decided that officers of the Volunteer Medical Service who transferred to the Territorial Force, but decided to remain with the Territorial Force unit into which their Volunteer unit was converted, do not retain the right to time promotion to the rank of lieutenant-colonel.

### Board of Guardians' Dispute with Medical Officer.

OBJECTION having been taken by a section of the Aberystwyth Board of Guardians to pay a charge of £1 rs. sent in by a local practitioner, who was called in by Dr. Bonsall, Medical Officer, to assist in administering an anæsthetic, it was agreed to submit the whole of the facts to the Local Government Board.

A reply was read from the Local Government Board at the meeting of the Aberystwyth Guardians on December 20th. The letter stated:—"The Board infer that the case was one of exceptional difficulty, for which a district Medical Officer would have been entitled, under Article 183 of the General Consolidated Order, to the sum of £2. They understand that Dr. Bonsall, under his contract, will only receive 15s. for the case, and that a charge of 21s. has, in fact, been made upon him by the anæsthetist for his necessary assistance in the emergency; so that if the guardians only repay 10s. 6d. of the amount, Dr. Bonsall's personal remuneration for his services in the case will only amount to 4s. 6d. The Board are sure that the guardians will recognise that this remuneration cannot be regarded as sufficient, and they trust that on further consideration they will be willing to repay the whole amount (21s.) of the anæsthetist's fee."

The letter was referred to the House Committee.

THE Wood Green, Hornsey, and Southgate Hospital will, it has been decided by the District Council, receive in future a grant of £120 per annum from the Wood Green Urban District Council.

## NOTICES TO CORRESPONDENTS, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

For ONE INSERTION:—Whole Page, 25; Half Page, 23 10s.; Quarter Page, 21 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at 23 10s.; 26 at 23 5s.; 52 insertions at 23, and pro rata for smaller spaces.

Small announcements of Practices, Assistantships, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

DR. J. C. T. (Bognor) is thanked for his communication, which, had it been received three weeks earlier, we should have been glad to announce.

RESPECT FINEM (Leeds).—The point stated by our correspondent is somewhat involved. If he will communicate with us more fully, we will be glad to advise him.

### HOTEL DIETETICS ON THE RIVIERA.

WE have received from the management of one of the large hotels (Hotel Prince de Galles) a letter announcing that "complete arrangements have now been made for providing an alimentary regime, which will give entire satisfaction to physicians sending patients." The diet tables are provided especially for patients suffering from stomach and nervous troubles, who are ordered a special regime, and the management of this hotel state that these are strictly prepared according to medical prescriptions.

EX ÆQUALI (Bridgewater).—The case is certainly one which is worthy of publication. If our correspondent will forward us his notes, we will find space to publish them.

M.R.C.S., L.R.C.P.—We cannot publish our correspondent's letter, since it deals mostly with points of present political controversy. Medical men, of course, are entitled to hold what political opinions they like, but the journals devoted to purely professional subjects are not the place in which to discuss them.

M.D., M.R.C.P.—Our correspondent is thanked for his communication, which shall receive early attention.

MOLAR.—Besides the two dental hospitals named, a complete dental department exists at Guy's, where the education for the I.D.S. can be obtained.

## Appointments.

- CLIFFORD, HAROLD, M.B.Lond., F.R.C.S.Edin., Registrar to the St. Mary's Hospitals, Manchester.
- COLLINS, G. F., L.R.C.P.Irel., M.R.C.S., Certifying Surgeon under the Factory and Workshop Act for the Sutton Bridge District of the County of Lincoln.
- FITZWILLIAMS, DUNCAN C. L., M.D., Ch.M., F.R.C.S.Edin., F.R.C.P.Eng., Surgeon-in-Charge of Out-patients at St. Mary's Hospital.
- GORDON, S. G., L.R.C.S., L.R.C.P.Irel., Assistant Resident Surgeon at the General Dispensary, Nottingham.
- HOBBS, EDWARD COOMBER, M.R.C.S., L.R.C.P.Lond., House Physician to the West London Hospital, Hammersmith.
- MCCULLY, D., M.R.C.S., L.R.C.P., House Physician at University College Hospital.
- MACMAHON, A. P., M.B., B.S.R.U.I., Certifying Surgeon under the Factory and Workshop Act for the Clondalkin District of the County of Dublin.
- RAYNER, H. H., M.B., B.Ch.Vict., F.R.C.S.Eng., Honorary Surgeon for Children at the Northern Hospital, Manchester.
- SHATTOCK, C. E., M.R.C.S., L.R.C.P., Obstetric Assistant to University College Hospital.
- SHAW, W. F., M.D.Vict., Pathologist to the St. Mary's Hospitals, Manchester.
- SIMPSON, GRAHAM, F.R.C.S.Eng., to the Lectureship in Operative Surgery in the University of Sheffield.

## Vacancies.

Manchester Children's Hospital (Out-patients' Department).—Assistant Medical Officer. Salary £100 per annum. Applications to H. J. Easton, Secretary.

- The Hospital for Sick Children, Great Ormond Street, London. W.C.—House Surgeon. Applications to the Secretary. Salary £30 for six months, washing allowance £2 10s., with board and residence in the Hospital. (See advt.)
- Liverpool School of Tropical Medicine.—Research Students on Malaria, Parasitology, and Pathological Chemistry. Salaries: £150 to £250 per annum. Applications to Professor Ross, University of Liverpool.
- Liverpool School of Tropical Medicine.—Research Assistant at the Runcorn Laboratories. Salary £120. Applications to Director, Crofton Lodge, Runcorn.
- Kent County Asylum, Chartham.—Third Assistant Medical Officer. Salary £145 per annum, with board, quarters, attendance, and washing. Applications to Medical Superintendent, Chartham, near Canterbury.
- Borough of Batley.—Medical Officer of Health. Salary £150 per annum. Applications to J. H. Craik, Town Clerk, Town Hall, Batley.
- Wye House Asylum, Buxton.—Assistant Medical Officer. Salary £120 per annum, all found. Applications to the Medical Superintendent.
- East London Hospital for Children and Dispensary for Women, Shadwell, E.—House Physician. Salary £75 per annum, with board, residence, laundry, etc. Applications to W. M. Wilcox, Secretary.

## Births.

- CORNWALL.—On Nov. 28th, at Westcliffe, Oconoor, the wife of Major J. W. Cornwall, I.M.S., of a son.
- HOTCHKISS.—On Dec. 20th, at Mid-Dykebar, Paisley, the wife of Robert Dunmore Hotchkiss, M.D., of a son.

## Marriages.

- PURDOM.—COUSINS.—On Dec. 21st, at Southend-on-Sea, William Percy Purdom, M.B., B.S.Lond., second son of Dr. and Mrs. Purdom, of Ellerslie, Park Hill Road, Croydon, to Violet Elizabeth, third daughter of the late Mr. W. C. A. Cousins, of London.

## Deaths.

- LLORD.—On Dec. 18th, at Mackay, Queensland, George Tyndale Lloyd, M.A., M.B., B.C.Oamb., only son of the late Rev. Thomas Lloyd and Mrs. Lloyd, of Slepe Hall, St. Ives, Hunts, aged 45. (By cable.)
- TAYLER.—On Dec. 17th, at Daitotei, Formosa, George Padgett Tayler, M.B., eldest son of G. O. Tayler, M.D., of Trowbridge, aged 35. (By cable.)

## OPERATIONS—METROPOLITAN HOSPITALS.

- WEDNESDAY.—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopaedic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Gt. Ormond Street (9.30 a.m.), Gt. ## NOVOCAIN and STRYCHNINE for Spinal Anæsthesia.

# NOVOCAIN

## Is the Non-Irritant Local Anæsthetic.

Manufactured by Meister, Lucius & Bruning, Ltd., Chemical Manufacturers,  
ELLESMERE PORT, CHESHIRE.

"NOVOCAIN is unequalled as an Anæsthetic in its freedom from  
irritant action on delicate tissues, and is of lowest toxicity."—Vide report  
BRITISH MEDICAL JOURNAL, March 27th, 1909, p. 783.

I. 6% Novocain Solution for Upper Dorsal Injection. Each Ampul contains:

NOVOCAIN . . . . . 0.06 gramme.  
Water . . . . . 1 cc.

One tube of Strychnine Sulphate contains 10 tablets, each containing 0.0005 gramme ( $\frac{1}{2}$  milligramme).

II. 15% Novocain Solution for Lower Dorsal-Lumbar Injection. Each Ampul contains:

NOVOCAIN . . . . . 0.15 gramme.  
Water . . . . . 1 cc.

One tube of Strychnine Sulphate contains 10 tablets, each containing 0.0005 gramme ( $\frac{1}{2}$  milligramme).

"These preparations do not decompose nor become discoloured."

# HOMMEL'S Hæmatogen

CONTAINS NEITHER ALCOHOL NOR ANTISEPTICS

A combination of 80 parts purified and concentrated Hæmoglobin  
with 20 parts chemically pure Glycerine and Aromatic Flavouring.

The best of all the existing preparations of Hæmoglobin. More efficacious than Cod-Liver Oil or the ordinary manufactured preparations of Iron. Very strengthening both for Children and Adults. An energetic Blood Former. Increases the Appetite. Aids Digestion.

**MOST SUCCESSFUL IN THE ANÆMIA AND GENERAL WEAKNESS CAUSED BY MALARIA.**  
ALSO IN IDIOPATHIC ANÆMIA, RICKETS, SCROFULA, DISEASES OF FEMALES, NEURAS-  
THENIA, WEAK HEART, PREMATURE DEBILITY in men. Useful in convalescence after  
acute diseases such as PNEUMONIA, INFLUENZA, and FEVERS.

FREE FROM BORIC ACID, SALICYLIC ACID, or other chemical preservatives of any kind, as certified by the independent  
chemical Analysis made by the Incorporated Institute of Hygiene, Devonshire-street, London, W.  
Contains along with purified Hæmoglobin all the salts of fresh blood, and valuable compounds of Phosphorus, such as Lecithin,  
Phosphate of Sodium, and Phosphate of Potassium, together with the important albuminous constituents of the blood serum, in  
a concentrated, purified, and undecomposed state.

**In prescribing, always state "HOMMEL'S" Hæmatogen as  
spurious imitations are offered.**

ONLY SUPPLIED IN FLUID, NOT IN CAPSULES OR OTHER FORMS.

Infants - - - Take from Half to One Teaspoonful twice a day in milk.  
Children - - - " One or Two Dessertspoonfuls daily, either pure or mixed with any convenient liquid.  
Adults - - - " One Tablespoonful twice a day before the two principal meals.

**READY THIS MONTH.**

IN THE "University Series" OF MANUALS.

**THE SECOND EDITION OF**

# **JELLETT'S MANUAL OF MIDWIFERY.**

## **PRESS NOTICES**

### **OF THE FIRST EDITION.**

THE MEDICAL PRESS AND CIRCULAR:—"We regard it as an excellent work. . . . The literary standard is a very high one, and the numerous illustrations are most attractive and helpful."

INDIAN MEDICAL GAZETTE:—"We have derived nothing but pleasure from the perusal of this work, the arrangement, type, and illustrations are excellent; and the subject matter is placed before the reader in a most pleasing manner."

INTERCOLONIAL MEDICAL JOURNAL:—"We have seldom read a book with so much satisfaction as this admirable compilation which appears in the 'University Series.'"

EDINBURGH MEDICAL JOURNAL:—"We have no hesitation in most cordially recommending this admirable text-book to both students and practitioners."

THE LANCET:—"A work of much thought and originality."

This, the Second Edition, is even better than the first; it has been for the most part rewritten and contains nearly 300 new illustrations.

**HUMAN HANDS  
HAVE NO PART IN MANUFACTURING**

*Antiphlogistine*

**(Inflammation's Antidote.)**

---

From the moment the ingredients are placed in the specially designed compounding machine until the nurse removes the finished product from the sterilized container at the bedside, every move in the making is done by machinery and under the most rigid antiseptic precautions. By preventing exposure it is possible to conserve to the highest possible degree Antiphlogistine's hygroscopic properties.

No plastic dressing can be mixed in a mortar box with a hoe, or in an ice cream freezer, or even with a druggist's mortar and pestle, and possess any scientific value. Its hygroscopic and osmotic qualities are necessarily ruined, owing to absorption of atmospheric moisture.

In using Antiphlogistine, the ORIGINAL and ONLY antiseptic and hygroscopic plastic dressing on the market, the physician knows that he is getting the BEST. Years of experience, specially designed machinery, a perfect container and the knowledge how, when and why, enable the originators of Antiphlogistine to turn out a remedial agent which in kind has never been equalled in the history of pharmaceutical manufacturing.

The wise medical man who believes in ORIGINAL products, which are always the BEST products, prescribes,

**"SCOTT'S Emulsion in Bronchial Catarrh."**

**"Most successful result"**

**"In renovating the diseased tissues."**

-----, Cockermouth, March 23rd, 1906.

**EVIDENCE:**

"Dear Sirs,—I have much pleasure in informing you that your valuable medicine, SCOTT'S EMULSION, was administered to my patient, who recently suffered from a troublesome attack of bronchial catarrh, with the most successful result in renovating the diseased tissues, assisting expectoration by the iodine and possible other ingredients which it contains, and as a nutrient. Please accept of my sincere and grateful thanks."

Faithfully yours,

-----, M.D., L.R.C.S. & L.M.,  
Certf. Fact. Surg.

15 oz. Bottle, with formula, free to any physician, surgeon, or certificated nurse desiring to test SCOTT'S EMULSION.  
SCOTT & BOWNE, LTD., 10 and 11 Stonecutter Street, Ludgate Circus, London, E.C.

# MILO FOOD

## A COMPLETE DIET FOR INFANTS.

**MILO FOOD**, being partly composed of milk, is complete and entire in itself, and requires simply the addition of water to make it ready for use. It is not merely an auxiliary, like other Infants' Foods, which require milk to be added in preparing for use.

Awarded the **GOLD MEDAL** at the **CAPE TOWN EXHIBITION**, also the

**Certificate of Merit by the Institute of Hygiene, London.**

Sample and pamphlet on "The Feeding and Care of Infants" sent free on application to  
**NESTLE and ANGLO-SWISS CONDENSED MILK CO., 6 & 8 Eastcheap, London, E.C.**

# MODERN THERAPY.

## Dyspepsia.

Probably most cases of indigestion are due to the inability to convert amylaceous foods into assimilable forms.

**Taka-Diastase** has been proved to be the most potent—as well as the most convenient—substitute for ptyalin and amylopsin when these are deficient. It is a pure vegetable amylolytic ferment, capable of rendering soluble 150 times its weight of dry starch in ten minutes, and much more in a longer period.

**Taka-Diastase** is far more effective than other forms of diastase, and incomparably superior to malt extract, the best of which according to a recent report requires thirty minutes to digest only fourteen times its weight of starch. Moreover, unlike these preparations, it is active in acid conditions of the stomach or in the presence of tea, coffee, alcohol, etc. (see articles in *The Lancet*, May 7th, 1898, and *The Boston Medical and Surgical Journal*, April 6th, 1899).

**Taka-Diastase** retains its activity in all climates. The dose is from  $2\frac{1}{2}$  to 10 grains.

### BIBLIOGRAPHY.

**AMYLACEOUS DYSPEPSIA.** "In no case did I find Taka-Diastase fail in giving good results."—*Lancet*, August 7, 1897.

**DYSPEPSIA.** Excellent results in many obstinate cases.—*Liverpool Med. Chir. Jour.*, Jan. 1897.

**GOUTY DYSPEPSIA.** Most gratifying results after everything else had failed.—*Lancet*, October 10th, 1903, page 1052. Also see *The Practitioner*, Feb. 1907, page 168.

**TUBERCULOSIS.** A powerful aid to nutrition and increased strength.—*Medical Magazine*, June, 1906.

**CHRONIC CONSTIPATION.**—"Often brings about a cure in the most obstinate cases."—*Therapeutic Gazette*, October 15, 1906.

**CONVALESCENCE.** Invaluable after typhoid, etc., for enabling the enfeebled digestive powers to assimilate carbohydrate dietary.—*Therapeutic Gazette*, Oct. 15, 1906.

### PREPARATIONS.

#### TAKA-DIASTASE POWDER.

#### TAKA-DIASTASE TABLETS.

Each contains  $2\frac{1}{2}$  grains of Taka-Diastase.

#### TAKA-DIASTASE, LIQUID.

One fluid drachm contains  $2\frac{1}{2}$  grains of Taka-Diastase.

#### TAKA DIASTASE with CHOCOLATE TABLETS.

Each contains 1 grain of Taka-Diastase. Specially adapted for the treatment of children.

\* \* \*

The following combinations are specially indicated where peptic digestion is impaired.

#### TAKA-DIASTASE and PEPSIN COMP. TABLETS.

Taka-Diastase	...	...	...	1 grain.
Pepsin, P. D. & Co. (1:3000)	...	...	...	1 gr. M.
Pancreatin	...	...	...	$\frac{1}{2}$ grain.

#### TAKA-DIASTASE, PEPSIN and STRYCHNINE TABLETS.

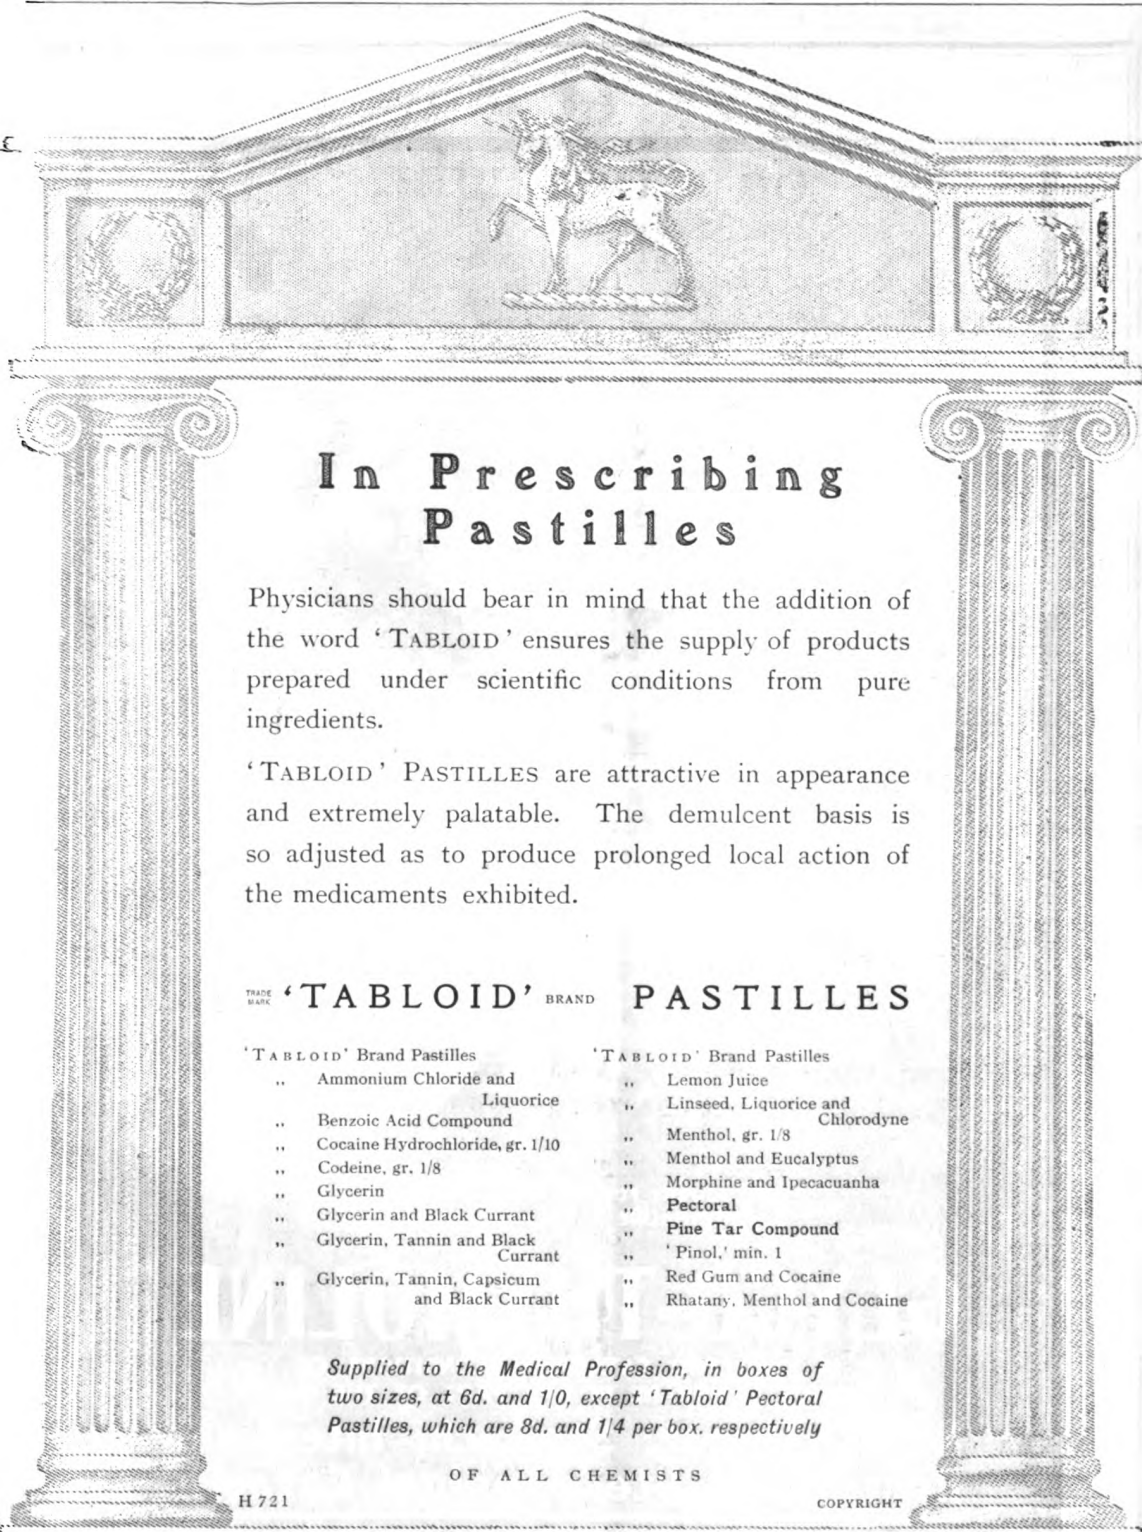

Taka-Diastase	...	...	...	2 grains.
Pepsin, P. D. & Co. (1:3000)	...	...	...	2 grains.
Strychnine Phosphate	...	...	...	1/100 grain.

Examined and approved by the INSTITUTE OF HYGIENE, 34 Devonshire St., Harley St., W., where their preparation can be seen, and its properties and value can be appreciated.

Have you noticed that an injection or instillation of

# ARGYROL

(SILVER VITELLIN)

relieves the pain of local inflammation, while all other silver salts increase the pain? Moreover, scientific studies prove that Argyrol quickly destroys gonococci.

These facts explain why Argyrol is considered, the world over, a superior remedy in the treatment of gonorrhœa (injection of 10 per cent. solution every three hours) and other inflammations of the eye, throat, nose and ear (25 per cent. solution instillation or local application).

Produced by

**A. C. BARNES COMPANY**

**32 SNOW HILL, LONDON, E.C.**

The following statement concerning

# OVOFERRIN

(IRON VITELLIN)

is a copy from the official records of the largest clinic in Germany where the remedy has been in continuous use for more than four years:

"Ovoferrin is an easily assimilable, well tolerated remedy which does not disturb digestion or cause constipation, but improves the appetite, digestion and general nutrition, and produces steady and progressive increase in the percentage of hæmoglobin and red corpuscles."

Ovoferrin is furnished by chemists, on prescription, in twelve ounce bottles. The dosage is one tablespoonful in a wine-glass of water or milk three times daily.

## Valentine's Meat-Juice

IN PNEUMONIA, PHthisis AND INFLUENZA.

Where a powerful and energetic nourishment is required in a concentrated, rapidly assimilated form, easily administered and readily tolerated, when other forms of food fail, Valentine's Meat-Juice is employed by well known practitioners throughout the world.

**Frank Van Fleet, M. D.,** *Professor Diseases of the Eye; Post-Graduate Medical School and Hospital, New York.* "My personal experience with Valentine's Meat-Juice has been very satisfactory. I was unfortunate enough to contract double Pneumonia last winter, which was followed by double Pleurisy and Empyema. During several weeks of unconsciousness I was nourished (after milk had begun to disagree with me) with Valentine's Meat-Juice exclusively."

**Dr. Andres Martinez Vargas, Madrid, Spain,** *Honorary President of the Congress for the study of Tuberculosis, Paris.* "I have used Valentine's Meat-Juice for the sick in my hospital, with most satisfactory results. I recommend it for its ease of absorption and entire organic assimilation and for its alimentary richness."

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

**VALENTINE'S MEAT-JUICE COMPANY,**

**TAMAR****A Laxative, Refreshing, and Medicated Fruit Lozenge.**

VERY AGREEABLE TO TAKE, AND NEVER CAUSING IRRITATION.

its physiological action assures  
the immediate relief and  
effectual cure of . . . . .**CONSTIPATION,****INDIEN****HÆMORRHOIDS, BILE, HEADACHE, LOSS OF  
APPETITE, AND INTESTINAL OBSTRUCTIONS**

By augmenting the peristaltic movement of the intestine without producing undue secretion of the liquids. Unlike pills and the usual purgatives, it does not predispose to intestinal sluggishness; and the same dose always produces the same effect—that is to say, never needs increasing.

It is recommended by the most eminent physicians of Paris, notably Drs. BÉLIN and TARDIEU, who prescribe it constantly for the above complaints, and with the most marked success.

# *The* **Allenburys'** **DIET**

**B**Y the use of the "Allenburys" Diet all trouble of peptonising milk and farinaceous foods is overcome. In the sick room it is invaluable, as the food is easily digested and assimilated, and only the exact quantity required need be prepared at a time.

The "Allenburys" Diet is made from pure full cream milk and whole wheat, both ingredients being partially pre-digested during manufacture. It can be taken by those who cannot digest cow's milk, and provides a light and very nourishing diet for Invalids, Dyspeptics, and the Aged.

For travellers by sea or land this complete food will be found exceedingly valuable.

Sample, with full particulars, sent free on request.

## PRIVATE ASYLUMS, HOMES, SANATORIA, &amp;c.

**ST. PATRICK'S HOSPITAL FOR MENTAL DISEASES.****THE GOVERNORS OF ST. PATRICK'S HOSPITAL, DUBLIN**

(FOUNDED BY DEAN SWIFT IN 1745).  
Wish to announce that they have acquired a large property, in accordance with their Royal Charter (200 acres), and established a Private Asylum in connection with the Hospitals at Lucan for the reception of patients of both sexes suffering from Mental Disease.

A NEW VILLA has been erected at Lucan for the accommodation of a limited number of gentlemen, and the entire establishment has been lighted by electricity.

The parent institution in Dublin continues its curative work, has undergone almost entire reconstruction, receives both male and female patients, and its recovery rate is very satisfactory. The Governors are anxious that the Medical Profession should be acquainted with the work of this historic institution, which has been devoted for over a century and a half to the reception and curative treatment of the insane of Ireland.

Urgent cases can be admitted by direct application to the Medical Superintendent.

For further particulars, forms of admission, &c., apply to the REGISTRAR, St. Patrick's Hospital, James Street, Dublin.

**PRIVATE ASYLUMS, Co. DUBLIN.**

**For the Cure and Care of Patients of the Upper Class Suffering from Mental and Nervous Diseases, and the Abuse of Drugs.**  
Established 1825.

**HAMPSTEAD, HIGHFIELD**  
**GLASNEVIN, FOR GENTLEMEN. DRUMCONDRA, FOR LADIES**  
Telephone, 1032.

These Hospitals are built on the Villa System, and there are also Cottages on the demesne (154 acres), which is 100 feet above the sea-level, and commands an extensive view of the Dublin Mountains and Bay.

*Voluntary Patients admitted without Medical Certificates.*

For further information apply for illustrated prospectus, &c., to the Resident Medical Superintendents, Dr. HENRY MARCUS EUSTACE, Highfield, Drumcondra, or Dr. WILLIAM NEILSON EUSTACE, Hampstead, Glasnevin; or at the office, 41 Grafton Street, Dublin. Telephone 198. On Mondays, Wednesdays and Fridays, from 2 to 3 p.m.

**THE ONLY ASEPTIC FEEDER MADE IS THE ROTUNDA FEEDING BOTTLE.**

It is simple—only a pure rubber teat and bottle—no valve. It is safe—for it can be sterilised. It is cheap—6d.

Can be had Wholesale from any Druggist's Sundry House, or from

**LEONARD & CO., Chemists, Dublin & Belfast.**  
Leonard's Rotunda Tissue, 1/- per lb.

Leonard's Clinical Thermometers, 1/- each.

**BIRKBECK BANK.**

ESTABLISHED 1851.

SOUTHAMPTON BUILDINGS, HIGH HOLBORN, W.C.

**2½ PER CENT. INTEREST**

allowed on Deposits repayable on demand,

**2 PER CENT. INTEREST**

on Drawing Accounts with Cheque Book.

All general Banking Business transacted.

ALMANACK, with full particulars, POST FREE.

C. F. RAVENSCROFT, Secretary.

**MEDICAL LOCOM TENENS.**

Subscribers placed on Register free of charge. Non-Subscribers charged a nominal fee to merely cover expenses.

Gentlemen requiring a Locom Tenens would act adversely by communicating with more than one applicant and selecting the most suitable.

It is particularly requested that all appointments will be duly notified to the Registrar.

Please address as follows: X 21, or X 22 (as the case may be): 18 Nassau Street, Dublin.

**STRETTON HOUSE,**

Church-Stretton, Shropshire.

A Private HOME for the treatment of Gentlemen suffering from Mental diseases. Bracing hill country. See "Medical Directory," p. 1958.

Apply to Medical Superintendent. Telephone 10 P.O. Church-Stretton.

**THE RETREAT PRIVATE ASYLUM**

Near ARMAGH.  
(ESTABLISHED 1824.)

Licensed for the reception of ladies and gentlemen of the upper and middle classes suffering from

**MENTAL AND NERVOUS DISEASES.**

(Voluntary Boarders and Inebriates admitted.) This establishment has lately undergone many structural alterations and improvements, and the walks and grounds are extensive and picturesque.

Great care and attention are bestowed upon the patients, outdoor and indoor games and regular carriage exercise being provided.

Golf links have recently been added.  
For further information apply to the Medical Superintendent, Dr. J. GOWER ALLEN, J.P., or Mr. JOSEPH ALLEN, Clonellan, Armagh.

**STEWART INSTITUTION**

**FOR IMBECILE CHILDREN, AND HOSPITAL FOR MENTAL DISEASES, Palmerston, Chapelizod, co. Dublin.**

This institution receives imbecile children from all parts of Ireland free, or by partial payment, by election. Full payment cases at moderate rates. One vote for every 10s. 6d. subscribed annually. A life vote for £5 5s. donation.

The Hospital for Mental Diseases—a separate establishment—receives lady and gentlemen patients from £50 per annum upwards according to accommodation required. Management fully up-to-date in all particulars. Beautiful situation. Best modern sanitation. Fine demesne, with necessary privacy. Voluntary boarders received.

Resident Medical Superintendent: Dr. F. E. RAINSFORD. All particulars from Secretary at Office, 40 Molesworth Street, Dublin.

DUBLIN.

**FARNHAM HOUSE**

For Gentlemen; MARYVILLE for Ladies.

**AT FINGLAS, NEAR DUBLIN.**

Licensed for the treatment of Diseases of the Brain and Nervous System. Particulars as to terms, &c., can be obtained from the Medical Superintendent, or at the Consulting Rooms,

40 GAY STREET, BATH.

Telephone: 21 Y Bath.

**POOR-LAW MEDICAL OFFICERS' LOCOM TENENS.**

Medical Officers seeking temporary substitutes, or practitioners willing to act as such, are requested to make application to the Locom Tenens' Registrar, Dublin Office of The MEDICAL PRESS, 18 Nassau Street, Dublin.

## MEDICAL GRADUATES' COLLEGE AND POLYCLINIC

22 CHENIES STREET, GOWER STREET, LONDON, W.C.

Cliniques are held daily at 4 p.m. (except Saturdays).

Lectures on the Practice of Medicine and Surgery and their Special Branches are delivered daily (Fridays and Saturdays excepted) at 5.15 p.m.

Medical Practitioners of either sex are eligible as Subscribers on payment of One Guinea annually.

Subscribers are entitled to the use of the Library, Museum, and Reading-rooms, to attend the daily Cliniques and Lectures, and to receive the "Polyclinic Journal" monthly.

Four Sessions of Practical Classes, each of six weeks' duration, and a Vacation Course of three weeks, are held during the year.

A detailed Syllabus of these classes can be obtained on application.

Special Tutorial Classes are held for gentlemen reading for the higher qualifications.

A Clinical Research Laboratory is attached to the College where specimens may be sent for examination and report at moderate fees.

A Complimentary Ticket, available for three successive days, will be issued to any Practitioner upon personal application at the College.

Full information may be obtained from the undersigned,

E. T. VINT, Superintendent.

PERMANENTLY CURED.

Booklet of Particulars and Testimonials from

Mr. A. C. SCHNELLE, 119 Bedford Court Mansions, LONDON, W.C.

## Preparations

### OF THE NATURAL DIGESTIVE PRINCIPLES

#### **Benger's Essence of Rennet**

(CURDLING FLUID)

This is most strongly recommended for making delicious and wholesome Junket or Curds and Whey. The process is very simple. A pint of milk is warmed and a teaspoonful of the Essence added. In five minutes the dish is ready for use. A shilling bottle is sufficient to make 32 pints.

*Dr. HENRY ASHBY, Physician to the Manchester General Hospital for Children, says in the "British Medical Journal":—"Mr. BENGER has recently prepared an exceedingly active and reliable curdling fluid, which I have put to some crucial tests, and I believe it will be found very useful in preparing whey, and will supersede the use of Rennet, or any of the essences."*

#### **Benger's Pancreatized Lentil Flour**

This flour is specially prepared for the use of children and invalids. It can be used in the same way as the well-known "Benger's Food" for which it may be substituted when a change of diet is thought desirable. Lentils form a highly nutritious food, being especially rich in nitrogenous material, and the method of preparation of this flour makes it easy of digestion.

#### **Benger's Pepsine Pills**

This represents the active principle of the Liquor Pepticus in the form of tasteless coated pills, and for those who prefer this form in place of the fluid, will be found equally convenient and effectual.

*The "MEDICAL TIMES AND GAZETTE" says:—"The 'Liquor Pepticus (Benger)' is singularly free from all disagreeable smell or taste; is clear and bright; and is a remarkably active Fluid Pepsine. It is worthy of all praise as a skilled preparation, and its high value as a digestive agent has been well proved by large experience."*

TO BE OBTAINED FROM ALL LEADING CHEMISTS, ETC., OR OF
